## FOREWORD

It is a distinct pleasure to be permitted to prepare a Foreword to the second volume of Children's Behavior Problems. The author has labored under most difficult circumstances to complete a well-conceived study—one which has utilized a wealth of material accumulated in a child-guidance clinic over a period of many years. This second volume by no means exhausts the possibilities for contribution to the growing understanding of children's problems.

The author is to be congratulated on the completion of these studies of "Relative Importance and Interrelations among Traits" of Children's Behavior Problems.

Paul L. Schroeder, M.D.

April 17, 1942

## EDITOR'S PREFACE

In this volume Dr. Luton Ackerson continues<sup>1</sup> his statistical analysis of the data upon children's behavior problems extracted from the case records of the Illinois Institute of Juvenile Research.

Dr. Ackerson, in truly scientific spirit, stresses the fact that this is an exploratory study undertaken without a conceptual framework or hypothesis and with the disinterested objective of finding how some 125 behavior problems are intercorrelated with one another—a monumental undertaking that would have deterred a less intrepid and persevering investigator.

The author admits certain difficulties involved in translating case data into statistically manipulable categories that generally lower but may sometimes increase the correlations. These difficulties are: (1) the selective factor involved in the admission of cases to the Institute, (2) the difficulty of ascertaining in quantitative terms the reliability and objectivity of subjective case-record information, (3) the preconceived notions of parents in making reports and of the staff examiners in diagnosing problems, (4) the lack of completeness of the case studies, (5) the inadequate definition of categories, (6) the use of categorical trait names instead of measured variates, and (7) the inadequate representation of desirable and presumably indifferent traits in the data.

No revolutionary discoveries are reported by the writer. The majority of the correlations are low, some moderately high, and a few quite high. Many of the rather high correlations are evidently due to the fact that what is essentially one characteristic appears under two or more different names in the case records.

---

<sup>1</sup>His early research upon the same data was published under the title Behavior Problems of Children: A Statistical Study Based upon 5,000 Children Examined Consecutively at the Illinois Institute for Juvenile Research, Vol. I: Incidence, Genetic, and Intellectual Factors (Chicago: University of Chicago Press, 1931).

Certain other correlations are, however, quite revealing. For example, Dr. Ackerson differentiates between "personality problems" and "conduct problems" and gives each individual a "personality-total" score and a "conduct-total" score. He then ascertains that, although these two total scores correlate for boys .50 with each other, the "personality-total" score has a correlation of only .19 with stealing, .18 with police arrests, and .09 with gang membership, but that "conduct total" show scores of .55 with stealing, .53 with police arrest, and .35 with gang membership. Evidently "stealing" is not significantly related to personality behavior problems but is associated with other conduct problems.

From this study can be drawn two points of value for future research. First of all, for statistical studies of a high order of determinacy a schedule of problems should be substituted for or be a supplement to the customary case-study recording. It is highly important that the same items be checked uniformly upon a standardized list. In the second place, helpful for further research is the series of intercorrelations mentioned above, in drawing up a smaller list of "problems" than the 125 problems of this investigation.

ERNEST W. BURGESS

## ACKNOWLEDGMENTS

To the late Dr. Herman M. Adler and to Professor L. L. Thurstone the writer is indebted for the preliminary arrangements for a comprehensive statistical study of children's personality and conduct problems based upon the material in a children's behavior clinic, of which this monograph represents a second volume. Our greatest debt of gratitude is unquestionably due the hundred or more present and former staff members of the Illinois Institute for Juvenile Research, who originally gathered this material and who, in addition to their full duties attendant upon the clinic care of cases, have held to the ideal of placing their work as completely as possible in record form suitable for research by others as well as by themselves. The devotion to research as one of the prime obligations of the Institute during the thirteen years of Dr. Adler's directorship has thus built up, not only a rich accumulation of well-kept case data, but also an attitude of encouraging original study continued under his chief-of-staff and successor, Dr. Paul L. Schroeder.

To Mrs. Myrtle Strom Mink the writer is indebted for advice in the interpretation of the social-history material; to Mrs. Muriel Highlander Lyon for varied assistance throughout all portions of the work; to Mr. William Melville and Mrs. Bessie Kight for clerical help; to Miss Margaret O'Connor and Miss Reba Gray for the statistical computations; to Mrs. Lilian Davis for critical aid with the manuscript; and to Mr. John C. Weigel for arranging the many affairs of personnel, equipment, and publication. A portion of the expense has been borne by the Behavior Research Fund and by the Work Projects Administration.

**PART I**  
**INTRODUCTORY**

## CHAPTER I

### THE PURPOSE

This volume deals with intercorrelations among children's traits, most of which are here grouped as "personality difficulties" and "conduct difficulties." The ultimate aim of our study, of which this book represents a second volume, is a quantitative investigation into the many causal factors underlying undesirable behavior manifestations in children.

The principle of multiple causality is the basis of our procedure.

It is assumed . . . . that behavior traits are correlated with a large number of factors either inherent in the child himself or arising in his environment, and that these correlations may vary in magnitude from zero to significantly high values either in a positive or in a negative direction. Thus the individual's behavior pattern is conceived as the resultant of many contributing factors of differing degrees of potency. The labor of this investigation consists in reducing to quantitative terms the degree of correlation or casual contribution.<sup>1</sup>

In accordance with such an empirical plan of attack the list of behavior traits studied was chosen on the basis of how frequently they were noted among our cases rather than according to any prevalent beliefs concerning their relative importance or seriousness. Specifically, all the traits whose incidences among our 2,113 White boys and 1,181 White girls seemed large enough to justify extensive statistical computations were selected for correlational analysis. Among characteristics or conditions other than behavior traits, only a few are discussed in the present inquiry. A more exhaustive examination of these non-behavior factors was not feasible at the present time.

Although our chief objective is the evaluation of causal factors, little will be said in this volume about causation in a

---

<sup>1</sup>L. Ackerson, Children's Behavior Problems, Vol. I: Incidence, Genetic and Intellectual Factors (University of Chicago Press, 1931). Pp. xxi + 268. Hereinafter referred to as Vol. I.

strict sense, for the calculation of correlations does not, of course, afford a final description of causality. It can under proper application state the amount of relationship and thus the amount of causation among a set of traits or conditions, this being its exclusive function, but it can never state the direction of causation. For if a correlation is obtained between trait A and B, the meaning may be (1) that trait A is the cause of trait B or (2) that trait B is the cause of trait A or (3) that both traits A and B, singly or jointly, are the effects of a third cause or group of causes, C. A fourth possibility, which is not usually stated specifically by writers on statistical technology but which is the most important one for research workers desiring to elicit unequivocal conclusions from actual data is (4) that a combination of two or more of the aforementioned factors may be present, e.g., traits A and B may react reciprocally upon each other and at the same time be influenced by a third cause or group of causes, C.

A concrete illustration will make Point 4 clear. Between the notations staying out late at night and sex delinquency (co-itus) among our 1,181 girl cases we have found the substantial correlation (Pearson's tetrachoric  $r$  with age partialled out) of  $.44 \pm .04$ . In this instance the causal interpretation is complex. The fact of staying away from home late at night probably exposes some girls to special temptations or opportunities for sex misconduct and may therefore stand as a direct causal influence. At the same time it is probable that girls of whom heterosexual activity has become a characteristic (the "aggressive" sex delinquents) may tend to stay away from home at night in search of conditions or companions peculiarly associated with misconduct of this type, so that the fact of sex delinquency thus may be to this extent the contributing cause. And at the same time both staying out late at night and sex delinquency may be effects of an outside cause or group of causes: e.g., if family control is inadequate and the girl is "allowed to run wild"; if the girl is on terms of hostility with other members of the family (e.g., the step-parent hypothesis), and may tend to stay away from home and seek the quasi-friendship associated with illicit sex relations; if the girl is "infatuated" with some man, i.e., "sexually suggestible by one individual," as one sociological writer has expressed it, and responds to his requests that she "go out with him"; if the girl

"craves excitement" or a "gay life," which to her imply such activities as "booze parties" or "picking up a fellow who has a car" if the girl in "looking for a job" arrives in such predisposing employment as "music shows," night clubs, or "taxi dancing academies"; or if the girl was engaging in prostitution, in which the economic motive may have had some part. Many other outside factors could readily be cited, which in certain instances or under certain conditions may be operative as causes of either "late habits" or sex misconduct.

Thus it becomes apparent that a strict determination of what is cause and what is effect lies outside the scope of correlational statistics as they are employed in this study. Therefore, with a view toward simplifying the presentation of our findings, the material of this volume will be considered only as correlations or associations between traits. The interpretation of this material from the standpoint of assigning causal influences would require additional data bearing perhaps more directly upon questions of causation. Many readers will probably not be content with considering correlations merely as correlations but will desire to make their own interpretation of causal factors implied therein. There is no reason why they should not do so, under the cautions noted above.

#### The Utility of Correlation Coefficients

If this volume expressly refrains from discussion of causation, in order to avoid at this time the interpretive intricacies involved in assigning cause-and-effect status, and covers only the eliciting of correlations, what is the utility of this lengthy presentation of correlation coefficients?

1. Although correlations cannot by themselves point out what is cause and what is effect, they do serve a useful function in locating where causation of some kind exists. Statistical correlation is but the quantification of John Stuart Mill's "method of concomitant variations,"<sup>2</sup> which has long been recognized by logicians as an instrument of causal analysis. The approach in our

---

<sup>2</sup>W. Brown and G. H. Thomson, The Essentials of Mental Measurement (London: Cambridge University Press, 1921), p. 97.

study has been largely empirical. In view of the nature of the case material available to us and in view of the relatively small body of proved research information now existing, upon which one could base the hypotheses necessary for a more refined research investigation in this field, it was felt that a systematic exploration of a large number of frequently appearing behavior difficulties would be the most efficacious plan of attack. From such an empirical analysis it is to be expected that certain relations will be elicited and specific hypotheses suggested, which can be investigated in more crucial studies especially set up for this purpose. In thus circumscribing the field in which causal factors may be looked for, the routine calculation of correlation coefficients contributes directly to the study of causation.

2. The study of causation is valued not merely as an end in itself but rather as a means toward the ultimate aim of prognosis and therapeusis or prophylaxis, to use the medical terms, or the aim of prediction and guidance, to employ the psychologist's words. The usual logic has been that when we have identified the causes of certain conditions we may proceed more intelligently to devise methods of treatment or prevention. Now it has often happened that effective methods of treatment have been discovered more or less by chance, without any complete working-out of the intermediate implications of causal analysis or etiology. For example, much of the use of specific drugs in the cure of physical disease has been the result of fortuitous discovery, without any clear understanding of the reason for their efficacy. In reference to our data, then, it is possible that in many instances a study of the intercorrelations between behavior traits and related traits or conditions may lead directly to the invention of practical methods of treatment or prevention, although an adequate knowledge of the underlying causal mechanism is lacking.

3. An extensive list of correlation coefficients, it is hoped, will possess some practical utility both for workers in a clinic and for parents or guardians in the following manner: A high correlation coefficient between two traits means that the two traits tend to be associated in the same individual. Therefore, if the presence of one trait in a given child has been ascertained, high correlation coefficients may often serve as clues to the presence of other traits not so easily ascertainable. A more detailed

discussion of this possibility will be given in chapter vii.

4. A similar possibility is that of prediction. If one of two traits which have been found from previous studies to be substantially intercorrelated is present in a given child, while the other trait has been ascertained to be absent, the question may well be raised whether the second trait may become present at a later time. Since a time factor is here admitted as a further complication, one's estimate of probabilities may be aided by a consideration of Volume I, Part III, in which the relation of behavior traits to the age factor was presented. A more complete explanation of this possibility of prediction is reserved for chapter vii.

Volume I dealt with the relation of children's behavior difficulties to sex differences, to racial (Negro-White) differences, to the developmental factor as represented by simple chronological age, and to the factor of intelligence as represented by mental age and intelligence quotient as obtained from an individual psychometric examination.

In the present volume, Part II deals with the correlations of 161 frequently noted behavior traits and other case-record notations, with three criteria designed to indicate the degree of the child's deviation from the conventional norm of acceptable behavior: (1) personality-total, i.e., the unweighted summation of all the personality problems reported for a given child, (2) conduct-total, similarly the unweighted summation of all the conduct problems reported for each child, and (3) arrest by police or appearance in juvenile court for reason of misconduct. A study of these correlations will throw light on the problem of the relative "seriousness" or "ominousness" of various behavior difficulties and may serve to point out which traits call for special attention.

Part III deals with 122 tables of correlation coefficients classifiable as follows: Tables 9 and 10, chronological age and intelligence quotient (IQ). These two tables cover much of the material of Volume I, Part III, but in the present volume the relationships are expressed in terms of correlation coefficients. Tables 11-116, inclusive, frequently appearing behavior traits. Tables 117-30, inclusive, case-record notations in the physical and psychophysical, the home and familial, and the educational and vocational fields which would not be considered as "behavior traits."

## CHAPTER II

### THE DATA

All the correlations reported in the present volume are based upon two groups of cases, 2,113 White boys and 1,181 White girls, except where otherwise explicitly stated. The boys and girls were never combined. They were children between their sixth and eighteenth birthdays, who were or had been in the regular public schools and whose intelligence quotients as obtained in the routine clinic examination (usually the 1916 Stanford-Binet) were 50 or more. Negro children, who comprised 408 out of the 5,000 cases originally covered in this investigation, were excluded because it was found that in our population they appeared to show a somewhat different sort of behavior complex than the White children (see Vol. I, chap. v). Children below 6 years of age and below 50 IQ were excluded from the total 5,000 consecutive cases, because it was found that our children below these age and intelligence levels manifested so few behavior problems (see Vol. I, Part III) that their inclusion would only inflate the correlation coefficients computed upon them. To "partial out" age and intelligence quotient would probably not overcome this difficulty successfully because of the frequent tendency toward curvilinearity of regression of trait on age or IQ, as shown in the curves in Volume I. There was excluded also a group of 90 boys and 98 girls of adolescent ages who were referred by "scholarship associations," primarily for advice as to whether their capacities justified the expenditure of the agencies' funds on their further education. The reason for this exclusion was that in the nature of things it was probable that their parents might be tempted to underemphasize any undesirable behavior traits which could militate against their obtaining scholarship grants. It is probable, moreover, that these children represent a very superior group in respect to personality traits and family morale, since they were planning on a high-school course which, even with the scholarship association's assistance of twenty-five dollars a month or less, would entail a considerable

financial sacrifice to the family.<sup>1</sup>

While these same factors of heterogeneity in motivation and selection could be urged for excluding some of the remaining cases, it was felt that they were too few in number to warrant their intentional omission: And, furthermore, too great a homogeneity in the material is not desirable, since a situation of complete homogeneity in any factors would render a correlational study of those factors impossible.

This arbitrary exclusion of cases described in the preceding paragraphs was made for the purpose of decreasing to some extent the divergence between our group of cases and an ideally unselected group of children of the same ages. That any sort of real approximation to unselected children of these ages has been achieved by these exclusions cannot, of course, be asserted. The many qualifying conditions surrounding the data, as far as the writer can see them, will be explained and discussed in detail in subsequent pages devoted to a description of our data and its source (chap. iv).

An extensive account of the source of our material and the circumstances under which it was obtained, together with the numerous factors influencing its validity, has been given in Volume I. Hence a brief résumé will be sufficient for the present.

All the children of this study have been examined at the Illinois Institute for Juvenile Research. A group of 5,000 consecutive cases who had a complete examination (psychiatric, psychological, physical, social, and, when requested, recreational) during the years 1923-27 provided the data.

The 2,113 White boys and 1,181 White girls concerned in this volume, it is well to repeat, were between their sixth and eighteenth birthdays at the time of their first admission, and their intelligence quotients were above 50 (Figs. 1 and 2).

The reasons for their being referred for examination may be found in Volume I, Tables 1-13. Most of the examinees provided a complex of reasons leading to their examination, so that one must

---

<sup>1</sup>A description of the group of scholarship children may be found in M. Raymaker (Worthington), "A Study of High School Scholarship Students," Institution Quarterly, XVI (Springfield, Ill.: Department of Public Welfare, 1925), 62-65.

not fall into the error of supposing that all in any group of children were referred specifically because of the trait under discussion. For example, our children with a notation of stealing include not only cases in which stealing was a major reason for their appearance in a behavior clinic but also cases in which stealing was only an incidental problem among many others. There appeared to be no practicable means of distinguishing "major" and "minor" reasons within our material.

Fig. 1.—Frequency Distribution of Chronological Ages

The character of the material may be roughly described as follows: The largest single group of children was referred because of behavior difficulties ranging from such relatively minor problems as finicky food habits to such serious problems as suspected insanity, illegitimate pregnancy, or alleged murder. The majority of these behavior difficulties concern the home, neighborhood, or school milieu. Only a fraction of the 3,294 cases discussed in this volume—about 22 per cent of the boys and 15 per cent of the girls—had a notation of police arrest or juvenile-court appearance for reasons of bad conduct, so that this group must not be thought of as "delinquents," a term which is best restricted to children who have been under police detention. That juvenile behavior difficulties are to a considerable extent prophetic of social or personal maladjustment in later life may be assumed. In

fact, the justification of the support by the Illinois State Department of Public Welfare of the Institute's clinical and research activities among these younger children lies in the possibility for prevention of such serious manifestations as criminalism or mental disease in later life which is afforded by this early care and study of childhood conduct and personality trends.

Fig. 2.—Frequency Distribution of Intelligence Quotients

The second largest single group of children presented problems of low intelligence and poor work in their school studies. Since our present group of cases includes only the children with intelligence quotients above 50, only a few of this group were referred for routine examination for commitment to a state school for mental defectives. Retardation in school (which would probably amount to two years or more by the age of 16) was noted in over 40 per cent of our 3,294 cases. In only a minority of instances, however, did inadequate intelligence or poor school work appear to be a principal reason leading to their being referred for examination.

Another large group presented problems of educational or vocational guidance not necessarily associated with low intelligence or general inadequacy in school work.

The remainder were referred for miscellaneous reasons, e.g., physical defects with which may be associated gross behavior difficulties, such as enuresis, convulsions, post-encephalitic conditions, endocrine disfunction, and the like, and various problems of foster-home placement and problems of future supervision.

It must be remembered that these descriptions do not represent any discrete or "official" classification of cases, since most of the children could be placed in two or more of these broad descriptive classes.

Most of the children live in or near Chicago. Their economic and cultural status ranged from very poor to very high but, in general, would be considered below average. A substantial fraction were of foreign-born parentage. Their intelligence level was generally below average (Fig. 2), although the grossly feeble-minded cases were excluded from our study.

The largest portion of the information was obtained from the child's parents, usually the mother, in a personal interview conducted by the psychiatric social worker. In the interview a social-history outline<sup>2</sup> was followed which "includes all the major points which should be covered in every case and which allows for expansion here and there according to the individual problems considered." Additional preliminary information was obtained from any social agencies with which the child or family had had a previous contact. In some cases supplementary information was obtained from other relatives or "friends of the family," from teachers, club-leaders, employers, etc. The rest of the information was obtained in the clinical examination itself, to which the psychiatrist was the chief contributor.

The data employed in this study are almost entirely in the form of categorical case notations, only four items—the personal-ity-total, the conduct-total, chronological age (CA), and intelligence quotient (IQ)—being in the form of continuous or measured variates. These categorical notations should be strictly interpreted as "noted or not noted" rather than as "present or absent."

<sup>2</sup> M. S. Mink and H. M. Adler, "A Suggested Outline for History-Taking in Cases of Behavior Disorders in Children," Welfare Magazine, VII (1926), 5-22. See also P. L. Schroeder, Child Guidance Procedures: Methods and Techniques Employed at the Institute for Juvenile Research (New York: Appleton-Century, 1937). Pp. viii + 362.

This caution is necessary in view of the fact that we cannot be sure that the absence of a specific notation means that the trait was non-existent in the child, since the amount or intensity of the interviewing was not necessarily uniform in each case (see pp. 35-38). Furthermore, in many of the more secretive or subjective behavior traits we cannot rely absolutely on the verity of the informant's observations and interpretations (see pp. 30-31). In the categorical notations as used in this volume no distinction was made between cases in which the grounds for a notation were well established and those in which the grounds were less certain. Our reasons for grouping the questioned and episodic instances with the unquestioned cases rather than on the "not-noted" side of the dichotomization are discussed on pages 31-32.

Our extensive use of these categorical and subjective case notations as research material raises many queries concerning not only the validity of the tetrachoric and bi-serial correlation methods necessary in treating such data but also the meaning of statistical results based upon such material. The next two chapters will attempt to discuss these technical problems in detail.

## CHAPTER III

### STATISTICAL METHODS IN CATEGORICAL DATA

The method of presenting the data of this volume is almost entirely by the comparison of correlation coefficients. These have been arranged in descending order, as far as possible, to facilitate comparisons with one another. Boys and girls are kept separate.

#### Pearson's Bi-serial and Tetrachoric Correlation Coefficients

Pearsonian correlation was used throughout. For the inter-correlations among the four quantitative variates—personality-total, conduct-total, chronological age, and intelligence quotient—product-moment coefficients were computed. For the correlations of these four quantitative variates with the categorical notations, Pearson's<sup>1</sup> bi-serial r was employed. For the intercorrelations among the categorical notations Pearson's<sup>2</sup> tetrachoric r, together with Everitt's tables of the tetrachoric functions,<sup>3</sup> was used. Probable errors of bi-serial r were obtained by Soper's<sup>4</sup> Formula 23 and his tables. Probable errors of tetrachoric r were obtained by

---

<sup>1</sup>A brief description of this bi-serial method may be found in I, 136. Its original presentation was given by K. Pearson, "On a New Method of Determining Correlation between a Measured Character A, and a Character B, of Which the Percentage of Cases wherein B Exceeds (or Falls Short of) a Given Intensity Is Recorded for Each Grade of A," Biometrika, VII (1907), 96-105.

<sup>2</sup>"On the Correlation of Characters Not Quantitatively Measurable," Philosophical Transactions of the Royal Society, London, CXCIV, Ser. A (1900), 1-47.

<sup>3</sup>K. Pearson (ed.), Tables for Statisticians and Biometricians, Part I (2d ed.; London: Cambridge University Press, 1924), pp. 1-1v and Tables XXIX and XXX. Since the time when the tetrachoric coefficients of this study were computed, a very efficient method has been devised for obtaining tetrachoric r's (L. Chesire, M. Saffir, and L. L. Thurstone, Computing Diagrams for the Tetrachoric Correlation Coefficient [University of Chicago Bookstore, 1933]), which yields coefficients of sufficient accuracy for almost all practical needs.

<sup>4</sup>H. E. Soper, "On the Probable Error of the Bi-serial Expression for the Correlation Coefficient," Biometrika, X (1914), 384-90.

Formula 213 in Kelley's textbook<sup>5</sup> and by his Table LI. For the coefficients smaller than .20 the computation of probable errors was omitted, partly because such probable errors would be very large in comparison with their coefficients and partly as a means of indicating that in view of the many possible distorting influences upon the coefficients (to be described in chap. iv) little interpretation should be made of coefficients below this size.

A brief explanation of these two coefficients may be desirable. Bi-serial  $r$  is computed from a tabulation such as the accompanying table, which shows the relation of depressed spells to chronological age among 2,113 boys, bi-serial  $r$  being  $.22 \pm .03$  (Table 9, pp. 128-29).

	Chronological Age											
	6	7	8	9	10	11	12	13	14	15	16	17
Depressed spells noted.....	5	3	6	8	9	14	18	16	19	24	20	7
Depressed spells not noted.....	82	119	170	181	200	215	225	223	234	161	99	55

This procedure assumes rectilinearity of regression in the continuous variate (chronological age) and normality of distribution in the dichotomized variate (depressed spells). The former assumption can be satisfactorily investigated for each tabulation by drawing up incidence curves<sup>6</sup> and observing their form. In the case of chronological age (CA) and intelligence quotient (IQ) it was obvious in Volume I, Part III, that in our data curvilinearity is the rule rather than rectilinearity. Our reasons for employing bi-serial  $r$  for these variates in spite of its admitted inadequacy are explained on later pages in this chapter.

The use of Pearson's<sup>7</sup> bi-serial  $\eta$  and "coefficient of class

<sup>5</sup>T. L. Kelley, Statistical Method (New York: Macmillan, 1923), p. 258. The original presentation was given by K. Pearson, "On the Probable Error of a Coefficient of Correlation as Found from a Fourfold Table," Biométrica, IX (1913), 22-27.

<sup>6</sup>I, 114-18, and Figs. 15-47.

<sup>7</sup>K. Pearson, "On a New Method of Determining Correlation When One Variable Is Given by Alternative Categories and the Other by Multiple Categories," Biométrica, VII (1910), 248-57.

heterogeneity or divergence"<sup>8</sup> (a two-row contingency coefficient), which make no requirements as to the form of regression in the continuous variates, did not appear serviceable in our material. These coefficients become seriously magnified by cell-frequencies of zero; and it was found after a brief experimentation that the large number of zero cell-frequencies in our data tended to exaggerate these types of coefficients beyond the limits of credibility.

It appeared best to compute bi-serial  $r$ 's routinely for each two-row tabulation and to accompany them with a verbal caution to the reader that these are only an inadequate substitute for the regular  $n \times n$ -fold scatter diagrams and product-moment coefficients and correlation ratios, which will not be obtainable until personality and conduct traits can be subjected to a satisfactory quantitative measurement.

There follows a specimen tetrachoric tabulation of the interrelation of stealing and truancy from home among 2,113 boys,  $r_t$  being  $.64 \pm .02$  (Table 56, p. 312).

	Stealing Noted	Stealing Not Noted
Truancy from home noted.....	375	128
Truancy from home not noted.....	440	1,170

As a means of economizing work in the computation of tetrachoric  $r$ 's, the following system was observed: The equation was first written out to the second power of  $r_t$  and solved. If the obtained coefficient fell between .30 and .49, the successive two terms up to the fourth power were added; and, for initial values of  $r_t$  of .50 or larger, the equation was carried out to the sixth power. It was found empirically that such short cuts seldom left the final  $r_t$  as far as .01 away from what would have been obtained with full carrying-out of computations.

Furthermore, in all coefficients in this volume, except

---

<sup>8</sup>K. Pearson, "On the Coefficient of Class Heterogeneity or Divergence," *ibid.*, V (1906), 198-203.

those for chronological age and intelligence quotient (Tables 9 and 10, pp. 128 and 130), chronological age was "partialed out,"<sup>9</sup> a process which in general had little effect upon the coefficients, since the correlations of age with the two notations in question were usually negligible. As a time-saving device, the partial coefficients were obtained from tables showing the limits between which the partial  $r$ 's would fall for various correlations with age. This short-cut process could only very seldom yield final coefficients differing as much as .01 from a stricter computation.

Among our  $r_{\frac{t}{t}}$ 's in Tables 6-130 it is possible, then, that, on account of the two short cuts just described, a few may differ as much as .02 from what would have been obtained under the strictest conditions of calculation; but, in view of the exploratory and tentative character of this research, this slight deviation from strict numerical accuracy is negligible.

Mention should also be made of the fact that the formula for the probable error of tetrachoric  $r$  is technically incorrect for our partial coefficients, involving as they do both tetrachoric and bi-serial methods. For such coefficients the probable error formula for tetrachoric  $r$  would give too large a value, while that for bi-serial  $r$  would give too small a value. Since the technically correct formula for this purpose has not yet been derived, it seems preferable to overstate rather than to understate the degree of unreliability attaching to these coefficients, and therefore the probable error for tetrachoric  $r$  was employed.

A correlation coefficient, it must be remembered, carries only a part of the implications of a relationship between traits. Wherever space permits, the tabulation upon which it is based should accompany it. The coefficient by itself, to be sure, probably represents the most essential element of the relationship. Because of its ease of computation it serves as a convenient measure of the amount of correlation between traits, and because of its compactness and universalized meaning it lends itself to use in comparative studies. These are the two uses made of it in this volume. But the worker who wishes more precise or complete information will need to refer to the original tabulations, at times

<sup>9</sup>G. U. Yule and M. G. Kendall, An Introduction to the Theory of Statistics (11th ed.; London: Charles Griffin, 1937), p. 269 (14.13).

even to the original protocols. He may wish to inquire into any irregularities in the relationship, whether it is rectilinear or curvilinear or whether a given population is homogeneous or heterogeneous, or he may wish to go beyond the abstract correlation coefficient to some more specific or practical application, such as eliciting clues to the presence of other important characteristics or the possibilities of predicting future behavior (see pp. 69-77 and Vol. I, chap. xii). When the role of the correlation coefficient in the total research process is considered, it is evident that obtaining the coefficient marks only the beginning stage and is not an end unto itself.

In order that bi-serial  $r$  and tetrachoric  $r$  may approximate the value of the standard product-moment  $r$ , the requirements underlying the two formulas should be fulfilled. These requirements are rectilinearity of regression in the case of quantitative variates and normality of distribution in the case of categorical notations, i.e., both formulas were derived from the product-moment formula on these assumptions. That is, we must assume that, if adequate measurements of the trends underlying the categorical notations could be obtained, they would be found to be normally distributed. In the absence of actual graduated measurement of trait notations such as ours, the fact of normality cannot, of course, be proved. The extensive employment of tetrachoric and bi-serial correlation in data of this kind, with its implicit acceptance of normality, is attributable to three lines of reasoning: (1) if many contributing factors of varying degree of potency may be effective in bringing about the presence of a given behavior trait and if this trait may be present in varying degrees of intensity, the resulting distribution of this trait in a population will be of graduated character and will tend toward normality of form;<sup>10</sup> (2) distributions actually obtained on measurable traits similar to ours usually show a symmetrical or bell-shaped form resembling Gaussian distribution, so that in the absence of specific knowledge as to the form of distribution, an assumption of normal or Gaussian distribution is better than that of any other one form;<sup>11</sup>

---

<sup>10</sup> A simple explanation of this point may be found in E. L. Thorndike, Mental and Social Measurements (New York: Teachers College, Columbia University, 1912), pp. 80-84.

<sup>11</sup> Ibid., pp. 94-105.

and (3) if the form of distribution is not grossly irregular, one may consider that, if an actual measurement device were constructed, it could be arbitrarily "scaled" to yield a normal or Gaussian distribution.

It should be remembered that the value of a bi-serial  $r$  or a tetrachoric  $r$  is not affected in any constant direction by the location of the point of dichotomization. The ideal point of dichotomization is near the centroid of the distribution. The effect of extreme dichotomies is a reduction in the reliability, which is (theoretically, at least) taken care of by the accompanying probable error.

Now a strict mathematical normality cannot be expected in actual research data. The question is whether the state of affairs of a specific research approaches sufficiently to a Gaussian distribution to warrant an acceptable interpretation of bi-serial and tetrachoric correlations in terms of the standard product-moment coefficient, with which we are more generally familiar. An empirical test was obtained by comparing tetrachoric  $r$ 's with product-moment  $r$ 's when both were computed from the same scatter diagrams found in statistical literature. In case of distributions approximating the normal, the two coefficients were generally similar, as one might suppose. But upon scatter diagrams whose variates showed extreme skewness and with extreme dichotomies, the discrepancy between the product-moment  $r$  and the tetrachoric  $r$  became so great at times that the two types of coefficients bore little resemblance to each other except in sign. It should be remembered, furthermore, that, when distortions from a true underlying normality of distribution are present, one cannot know in any instance whether they have the effect of increasing or of decreasing the  $r_t$  in comparison with a corresponding product-moment coefficient. It is probable, however, that in our categorical data the departure from strict normality was seldom so great as to invalidate entirely the meaning of our tetrachoric and bi-serial correlations within the latitude of interpretation of this study.

#### Other Correlation Methods for Categorical Data

As a means of escaping bothersome questions concerning assumptions as to the form of distribution of categorical notations,

some workers have avoided Pearson's tetrachoric and bi-serial correlation coefficients in favor of methods which make no such assumptions. Some workers have also preferred procedures less laborious of computation, but this can hardly be a worth-while advantage in working with material intended for publication, since the availability of simplified methods of calculation described above minimizes this difference in labor of calculation. Some of these methods are coefficiential, such as Yule's coefficient of association ( $Q$ ) or his coefficient of colligation ( $\omega$ ) or the fourfold contingency coefficients,<sup>12</sup> and some are quantitative indices; such as P (probability).<sup>13</sup>

While all these methods afford a measure of correlation or association between categorical notations, it must be pointed out that the values obtained by their use bear little or no functional relation to those of the standard product-moment correlation coefficient but must be interpreted, each within its own system of numerical indices. This lack of standardized or universalized meaning in the Q,  $\omega$ , and fourfold-C coefficients seems to the writer to constitute an important objection to their use. While there is an undeniable strength of position in employing techniques requiring no special assumptions in dealing with a categorical and subjective notation when one can neither prove nor disprove the validity of such techniques, it should be remembered, nevertheless, that, while these techniques impose no assumptions, at the same time they tell us little. Even at their poorest, the Pearson tetrachoric and bi-serial techniques can do as much as the Q,  $\omega$ , and fourfold-C coefficients. For if one disregards the assumptions and is willing to consider the coefficients as a unique system without thought of any relation or resemblance to the product-moment family of coefficients, one still has a "coefficient of association," whose derivation is equally plausible with Q,  $\omega$ , or fourfold-C. The raison d'être for assumption of normality of

<sup>12</sup>These coefficients are described in Kelley, op. cit., pp. 259-71.

<sup>13</sup>K. Pearson, "On the Criterion that a Given System of Deviations from the Probable in the Case of a Correlated System of Variables Is Such that It Can Be Reasonably Supposed To Have Arisen from Random Sampling," Philosophical Magazine, L, Ser. V (London, 1900), 157-75, and "On the Probability that Two Independent Distributions of Frequency Are Really Samples from the Same Population," Biometrika, VIII (1911), 250-54; R. A. Fisher, Statistical Methods for Research Workers (7th ed.; Edinburgh: Oliver & Boyd, 1938), pp. 81-85.

distribution is that the coefficients may be understood as an approximation to the values obtained from product-moment correlation. Therefore, the use of Pearson tetrachoric and bi-serial methods affords not only the meaning of a "coefficient of association" but gains the additional advantage of a fair likelihood that the coefficients may approximate the values of the universalized product-moment correlation.

Yule's  $Q$  and  $w$  coefficients have been vigorously criticized by Heron and by Pearson and Heron<sup>14</sup> on the grounds not only of their incomparability with the standard product-moment coefficient but also of their greater instability under changes in the point of dichotomization.

A fourfold mean-square-contingency coefficient,  $C$ , has several disadvantages: (1) its values do not approximate product-moment correlation except under special circumstances; (2) its values are without sign, i.e., they measure merely the divergence of a given fourfold table from one which would occur in the complete absence of interdependence or association between the two traits under discussion and cannot indicate whether the inferential relation or association is "positive" or "negative"; and (3) the maximum value obtainable by a contingency calculation on a 2 x 2-fold table according to Yule and Kendall<sup>15</sup> is .707, so that very high correlations cannot be adequately measured by a fourfold  $C$ .

The methods of expressing the amount of correlation—or, more precisely, non-independence—between traits in terms of probability indices, such as  $P$  (the probability that a distribution as divergent as the obtained one, or more so, could have occurred purely from random sampling in actually uncorrelated material), and the more conventionalized "critical ratio" (the ratio of a difference between percentages to the standard error of that difference) are faultless enough from the standpoint of sheer statistical logic. But, from the standpoint of simple interpretation or understanding, these probability indices possess marked disadvantages

<sup>14</sup>D. Heron, "The Danger of Certain Formulae Suggested as Substitutes for the Correlation Coefficient," Biometrিকা, VIII (1911), 109-22; K. Pearson and D. Heron, "On Theories of Association," Biometrিকা, IX (1913), 159-315.

<sup>15</sup>Op. cit., pp. 68-69.

in comparison with correlation coefficients of the product-moment family, such as Pearson's bi-serial  $r$  and tetrachoric  $r$ . The latter coefficients may take values ranging from zero to  $\pm 1.00$ , while probability indices may take values ranging from zero to infinity. Because of their compact range of values, the meaning of individual correlation coefficients becomes appreciable upon the briefest experience with them.

A more important drawback of a probability index is that it is a function not only of the underlying differences in the traits of the two groups but also of the number of cases upon which it is computed.<sup>16</sup> In fact, if a true trait-difference exists at all between two groups, whatever its amount, the index may be systematically raised to infinity by the simple expedient of increasing the number of cases. In actual practice, then, the probability index or "critical ratio" often becomes more a measure of the number of cases involved than a measure of the true underlying trait-difference. For this reason, such an index must be interpreted only with reference to the number of cases upon which it is based. Therefore, such indices cannot be used in comparisons unless the experimental populations are of uniform size. For example, in the present volume it would have been impossible, by the probability methods, to make comparisons between the boys' and the girls' correlations, since their populations were 2,113 and 1,181, respectively. The chief utility of these probability methods lies in establishing the degree of assurance that a difference actually exists.

Correlation coefficients, on the other hand, are not functionally related in any meaningful extent to the number of cases upon which they are computed beyond the conventionalized minimum of 20 or 30 cases<sup>17</sup> but measure purely the underlying correlation. This does not mean, of course, that the use of correlation coefficients evades entirely the implications of probability, "the

---

<sup>16</sup>Fisher, *op. cit.*, pp. 94-95.

<sup>17</sup>Even on smaller samples the systematic distortion in the central or expected values of product-moment coefficients is for most practical purposes negligible. See H. E. Soper et al., "On the Distribution of the Correlation Coefficient in Small Samples," Appen. II to the papers of "Student" and R. A. Fisher, in *Biometrika*, XI (1917), 328-413, esp. Table A.

fundamental problem of practical statistics,"<sup>18</sup> since they, like all other measures of trend or relationship based upon samplings of variate material, must be interpreted with some regard to their accompanying probable errors. But the correlation coefficient coupled with its probable error forms a compact quantitative expression which varies only within somewhat narrow limits with increase in the number of cases. The fact of this comparative stability of bi-serial and tetrachoric  $r$  under varying conditions of mere sampling constitutes an important advantage of these coefficients over the use of probability indices.

Although the tetrachoric coefficient has been in use among the English biometricians since 1900 and is described fully in most of the advanced statistics textbooks, it is only in recent years that more than a limited use has been made of this method of treating categorical data among other workers in the social sciences.

## CHAPTER IV

### THE VALUE OF CASE-RECORD NOTATIONS AS RESEARCH DATA

The preceding chapter described the statistical methods employed in this study and attempted to point out to what extent they conform to the requirements of our case-record data. In this chapter it is desirable to turn to a discussion of this case material from another standpoint, namely, its validity.<sup>1</sup>

In dealing scientifically with the gross patterns of individual human behavior, the problem of validity is a more critical matter than in the physical and biological sciences. For in the latter sciences many of the most important basic concepts can be clarified once for all by the simple expedient of an arbitrary definition of terms or units of measurement, and the validity or meaning of such terms is automatically established. In human behavior, on the other hand, workers cannot so readily resort to arbitrary definition to clarify concepts. Overt behavior manifestations are a matter of familiar knowledge, however superficial, to the layman and have already acquired firmly established popular names. The social scientist, therefore, has not the same opportunity to define once for all the phenomena with which he works but must frequently conform to this established usage of terms, however ambiguous or misleading it may be. While the question of validity involves more than an agreement on the definition of terms, concepts, or units of measurement, the fact remains that much of the problem of validity, as it is encountered in actual researches, would disappear if a universalized system of concepts were available.

The evaluation of case-record notations as research data raises the following points of validity, which will be discussed at some length in subsequent pages: the selective factors influencing the admission of children to clinic examination; the

---

<sup>1</sup>A critical discussion of our use of case-record data is given in a review of Vol. I by Ruth E. Arrington, Journal of Criminal Law and Criminology, XXIII (1932), 515-16.

reliability and objectivity of this sort of data, as psychometricians use these terms; the prejudicial effect upon correlation coefficients arising from prevalent beliefs or biases on the part of informants or examiners; differential completeness of the case-record information; inadequate defining of terms and ambiguous and overlapping grouping of notations; the use of categorical trait names instead of measured variates; and the inadequate representation in most case-record data of the desirable or indifferent traits, as distinguished from undesirable traits, i.e., the underrepresentation of "assets" in the child's behavior makeup and the overrepresentation of "liabilities."

#### The Selective Factors Influencing the Admission of Children to Clinic Examination

A glance at Figures 1 and 2 (chap. 11) indicates that our cases at the outset form a selected group on the basis of age and intelligence level. The age distributions in our material do not show an even distribution of cases at each age level, as one would expect among unselected children of this age range, but show increasing frequencies from 6 years up to about 13 or 14 years and decreasing frequencies beyond these levels through the seventeenth year. In our correlational results, chronological age has been "partialled out," but because of the frequent curvilinearity of regression of behavior problem on chronological age (Vol. I, Part III) the selective influence of age is probably not adequately cared for by the simple expedient of partial correlation.

The average intelligence quotient of our cases falls in the eighties. The exact average IQ of unselected children of these ages is still a matter of controversy, but in any event one can be sure that the cases of this study include a disproportionate number of children of below-average intelligence. A further selection enters through the fact that children with IQ's below 50 were arbitrarily excluded from the present study (see p. 9)—a factor which is probably of little import to our present problem.

In all probability there has also been a marked selection on the basis of cultural and economic status. These factors ranged from very low to very high among our cases but in the main would be considered well below average. The major portion were born in the Chicago metropolitan area. Over half of the parents were

foreign born, the largest foreign-born groups coming from "Russia," Poland, Italy, Germany, Austria, Hungary, and Rumania.

Probably the most serious selective factor, in the estimation of most readers, arises from the overweighting of cases manifesting marked personality and conduct difficulties.

There were enough children referred for other reasons than behavior difficulties, however, to prevent our material from being entirely homogeneous—for example, children referred because of difficulty in school studies or for vocational guidance or for advice regarding foster-home placement. But in general the divergence between our material and a group of ideally unselected children is probably sufficient to alter significantly the values of our correlation coefficients from what would have been obtained upon unselected material if it had been available.

A mitigating circumstance, however, lies in the fact that the selection on the basis of severity of behavior problems is probably a regular one and not an erratic one. The frequency distributions of behavior difficulties (Figs. 3 and 4) are generally regular and continuous. Therefore, one may hope that our correlation coefficients based upon this selected material may bear enough resemblance to the true state of affairs to suggest trends which may at some time be ascertained more precisely upon more representative material. Inasmuch as the effect of selection in our data appears to be a more or less regular "restriction of range," the expected result is a diminution in the size of the obtained correlation coefficients. The effect of selective factors alone, then, in contrast to some other influences to be described later, is an understatement rather than an overstatement of the true prevailing trends.

The problem of avoiding selective influences in the gathering of research data is one of the most difficult problems confronting the worker in the social sciences. When the material involves intimate facts in the behavior of people and their children, no mere matter of diligence, perseverance, or sincerity on the part of the worker will induce most persons to tell openly of such "family skeletons" as police records, psychoses, pauperism, illegitimate pregnancies, and the like, even under the confidential conditions of a psychiatric clinic. It is entirely possible that at some future time people will take a more objective attitude toward

undesirable or unsanctioned behavior among members of their families, but for the present the researcher who desires to study the more intimate and confidential facts of human behavior must content himself with material obtainable from informants who are willing to offer this information in return for the assistance which child guidance and mental-hygiene clinics can give them in their own problems. The task before the researcher, then, is to elicit information of more general applicability from material admittedly subject to selective influences. From such data, trends may be discernible which may be substantiated from other sources.

#### The Unknown Factors of Reliability and Objectivity

"Reliability" and "objectivity" are used in this chapter in the strict sense as used by psychometricians. "Reliability" is the correlation or agreement between the results of independent observations upon the same phenomena made by the same observer. "Objectivity" is the correlation or agreement between the results of observations upon the same phenomena by different observers. The fact that psychometricians have appropriated these words which are in common use and have restricted them to a very specific statistical meaning has aroused considerable objection on the ground that these words have already acquired in popular usage a much broader connotation which commonly includes the idea of dependability, trustworthiness, or truthfulness, to which psychometricians have given the separate technical term, "validity." The psychometrician's use of the concepts "reliability" and "objectivity" concern strictly only the consistency of different takings of the measures and not their truthfulness. In deference to this objection against the terms, and as a collective term to include the ideas both of reliability and of objectivity, we shall employ the word "consistency" in this discussion to refer jointly to both ideas.

The well-made research based upon variate and "fallible" data should include the formal presentation of reliability or objectivity coefficients.<sup>2</sup> These serve at least three essential purposes.

---

<sup>2</sup> A valuable discussion of this point is given by T. L. Kelley, "The Reliability of Test Scores," Journal of Educational Research, III (1921), 370-79.

1. In the case of an obtained zero-relationship between two variates, the researcher cannot know whether the underlying correlation is actually negligible, regardless of the adequacy with which the two variates in question have been measured or, on the other hand, whether the present measurement of the two variates was so faulty that they could not yield any outside correlations of significant size, even though actually the two variates are substantially correlated.

2. In case a consistency correlation is found to be zero, the researcher may either drop the given variate from further consideration or improve its method of measurement until its consistency is large enough to "support" outside correlations.

3. Knowing both the correlation between two variates and the consistency correlations of each variate, the researcher may infer the theoretical maximum correlation which would be obtained if the two variates were perfectly measured, i.e., the so-called "correction for attenuation"<sup>3</sup> or, similarly, the theoretical correlation which would be obtained under given degrees of improvement in the consistency of measurement of the two variates.

It has become evident to the reader that the attitude taken in this discussion toward reliability and objectivity is that these are very definite mathematical indices, to be computed in very specific ways, and not mere impressionistic and categorical expressions. The assertion that a certain datum is reliable or not reliable, or objective or not objective, is next to meaningless. What we wish to know, rather, is whether its reliability or objectivity coefficient is as high as .90, or only .50, or as low as .30. Having this information, we are enabled to conclude whether the research data in a given instance are suitable for the purpose in view. While the use of these consistency correlations fits most conveniently into a straightforward coefficiential correlation methodology, it must be remembered that the same factors of reliability and objectivity function just as importantly in other types of correlational research, whether by group differences, probability indices, or graphical representation in curves and the like.

---

<sup>3</sup>C. Spearman, "Demonstration of Formula for the True Measurement of Correlation," American Journal of Psychology, XVIII (1907), 161-69, and "The Coefficient of Correlation Calculated from Faulty Data," British Journal of Psychology, III (1910), 271-95.

In the material of this study, which is composed almost entirely of subjective notations made by parents and examining staff, the lack of consistency correlations is painfully conspicuous. From our case material there appeared to be no feasible method of obtaining these correlations. Ordinarily, there was only one person who served as the source of information. In the home and developmental history of the child it was possible occasionally to obtain interviews from both parents of the child. A cursory comparison of such paired interviews, one from each parent, disclosed that in the great majority of instances the two parents agreed substantially in their accounts of the child's behavior. There were a few instances, however, in which the parents gave contradictory information on the same items. The amount of agreement or disagreement between the two parents, however, cannot be taken as an adequate measure of the objectivity of these case notations, since in most instances they have probably been considerably influenced by each other in their attitude toward the child's behavior, so that their statements really represent a joint belief or consensus of opinion. To ascertain the amount of agreement between the mother and some informant outside of the family would not obviate this difficulty. Since the largest part of our data concerns the child's behavior in the home and neighborhood, other informants are not likely to possess much knowledge beyond that which the child's parents have given them, so that these two sources of information would not be ideally independent sources. In short, there seemed to be no satisfactory source of parallel information to employ as a measure of the objectivity of the mother's statements.

The other principal source of our data was the case notations of the examining staff. It would not be impossible to make a fairly adequate study of the objectivity of this type of data. The difficulties, however, would be large: (1) the expense of providing parallel staff members, (2) the tendency of members of the same clinic to conform to certain schools of thought or modes of practice, and (3) the fact that the child-guidance field is still so largely uncharted and systems of interpretation of human behavior still in such a state of flux that studies of subjective case notations made at this stage may within a few years become obsolescent.

The study by Willard C. Olson presents encouraging evidence as to the reliability and objectivity of categorial and semi-

categorical case notations. He employed a cross-on-a-line rating scale modified by the inclusion of five landmarks in each trait, each rating being weighted according to a previously derived criterion of relative importance or seriousness. Thirty-five behavior traits were separately rated on 182 school children in Grades I-IV. Repeated ratings were obtained from their teachers. The reliability or consistency correlations for the 35 separate traits ranged from .33 to .81. The intellectual traits were rated most reliably (average  $\bar{r}$  = .69), followed by social traits (average  $\bar{r}$  = .61), then the physical traits (average  $\bar{r}$  = .55) and, least reliably, the emotional traits (average  $\bar{r}$  = .51).

Traits with readily observable trait actions were rated most reliably. Thus for the trait, "Is he slovenly or neat in personal appearance?" ( $\bar{r}$  = .81.) Similarly for the trait, "Is he quiet or talkative?" ( $\bar{r}$  = .80.) On the other hand, traits that called for more elusive interpretations of behavior were rated less reliably. "Does he lack nerve, or is he courageous?" ( $\bar{r}$  = .33) and "Does he give in or does he assert himself?" ( $\bar{r}$  = .37) are examples of traits with low reliability.<sup>4</sup>

These reliability coefficients are not so high as one could wish but are in the main high enough to justify their use in correlational studies. While they were obtained under conditions quite different from those of our study, there is no reason to suppose that the consistency of our case notations, if it were obtainable, would be found to be greatly different.

The many ways in which the subjectivity factor may show itself in our case notations scarcely need describing. The informants, usually the child's mother, vary all the way from those possessing a good knowledge and understanding of their children's behavior and adequate language to express themselves down to mothers unaware of the true state of affairs and with poor powers of discernment and interpretation. Parents differ also in their standards of noting a behavior item as important. An overanxious mother will probably remark many more behavior problems in her children than a more easygoing or less protective mother. Therefore, we cannot assume that the line of demarcation between such traits as overinterest in the opposite sex and a merely normal sex interest

---

<sup>4</sup>Problem Tendencies in Children: A Method for Their Measurement and Description (Minneapolis: University of Minnesota Press, 1930), pp. 25-32 and Table XXVI.

is uniform for each child in our series. A quarrelsome or scolding mother may by her actions engender or enhance behavior traits in her children, which under more skilful parentcraft might not have emerged to the same conspicuous degree. Thus the notations concerning a child's behavior really measure not only the child's intrinsic personality and conduct but also the attitude or behavior of other persons toward him. In short, the effect of the subjectivity factor on the part of informants is to bring about a lack of uniformity in the conditions under which the data are gathered.

Three other problems arise in connection with the subjectivity factor: (1) prejudicial attitudes or beliefs on the part of the informant or the examining staff, (2) the varying completeness of the case material, and (3) inadequate defining or grouping of terms by the indexers. These are important and distinctive enough to warrant separate discussion in later pages.

There are two elements in the situation, however, which tend to counteract to some extent the lack of uniformity occurring through variability among the informants. One is the fact that the interviews are conducted by experienced psychiatric social workers or by students in training under their supervision. Their aim is to elicit as far as possible the truth underlying the informant's statements. The other is the fact that the members of the examining staff are obliged to come to some conclusion and make recommendations concerning the child's future care. For that reason the case record is not considered complete until the staff is satisfied that adequate information covering the child's social, mental, emotional, and physical status has been obtained. There arises the danger that an interviewer, if markedly domineering or biased, may inject an additional element of subjectivity into this sort of data. It seems more probable, however, in view of the uncertain quality of most informants, that case information obtained and recorded by a trained interviewer, such as a psychiatric social worker, will lie closer to the truth than data based upon the unchecked statement of the child's parents.

A further factor in the reliability and objectivity of our case notations concerns the items about which the informant or staff member is uncertain. For example, if the mother suspects that the child steals but has had no convincing evidence, should the child be placed among the "stealing noted" group or among the

"stealing not noted" group, or should he be placed in a separate "question of stealing" group? It was possible to make an empirical test of the matter. For some of the more frequently noted traits, such as stealing, stubbornness, sex delinquency (coitus), or psychoneurotic trends, subclassifications were made for "question of" and occasionally for "episode of." Parallel bi-serial and tetrachoric correlation coefficients and also incidence curves were computed with the "question of" cases placed first on one side of the dichotomy and then on the other side. It was quickly found that the coefficients and curves obtained from pooling the questioned and episodic cases with the "noted at present" group usually showed a slightly higher correlation than by considering them in the "not noted" side of the dichotomization. This fact was taken as an indication in favor of including them in the "noted as present" group. The diminishing of the size of the correlations consequent upon the other system of grouping was interpreted as due to a neutralizing effect upon the underlying correlation, which would result if a case were placed on the wrong side of the dichotomization.

A further source of attenuation in the obtained correlations arises from the fact that the "not noted" category includes both the cases in which the trait was absent (or present only to an inconsiderable degree) and cases in which the item was unknown or unrecorded. In the specific list of traits discussed in this volume,<sup>5</sup> however, this element of uncertainty is probably not of great importance, since these more frequently appearing traits were fairly diligently inquired into at the time the case information was obtained. Furthermore, in the present research the aim is exploratory and only marked relationships are sought for. Therefore, any trends which are so tenuous as to be blurred seriously by these crudities of measurement are too slight to be given attention in this study. In a more conclusive ad hoc investigation of some specific question or hypothesis such a tolerant attitude toward imperfections in one's data would be quite undesirable and inexcusable. In anything approaching a refined study based upon case-record notations it would be necessary to distinguish rigidly between "unknown" and "negative" items.

---

<sup>5</sup>Chap. v.

The effect of a lack of reliability or objectivity in the measures, as described in the preceding paragraphs is an "attenuation,"<sup>6</sup> or constant tendency toward reduction in the size of correlation coefficients based upon such data. The error arising from this factor alone (in contrast with the effect of certain factors to be discussed in subsequent pages) is fortunately one of understatement, rather than of overstatement, of existing trends.

While there is no entirely satisfactory substitute for consistency correlations as obtained from a routine calculation upon repeated measures, there exists, however, an indirect indicator of the presence of reliability or objectivity which has some degree of utility in actual research situations. If  $r_{ab}$  represents the correlation between traits A and B, and if  $r_{a_1a_2}$  and  $r_{b_1b_2}$  represent the consistency correlations of the two traits, Kelley<sup>7</sup> has shown that the maximum correlation of  $r_{ab}$  cannot, except as a matter of chance, exceed  $\sqrt{r_{a_1a_2} \times r_{b_1b_2}}$ . If any trait, then, manifests a tendency toward substantial correlation with other traits, it is highly probable that the trait in question possesses a workable amount of reliability and objectivity, for, if either consistency correlation under the radical were zero, the intercorrelation between these two traits could not be expected to attain a significant size unless some fortuitous combination of subtle factors were present.

While the fact of substantial outside correlations argues in favor of the consistency or stability of the data, the fact of zero outside correlations does not necessarily mean that the reliability or objectivity of the data is low. In the latter case the meaning is indeterminate. A zero outside correlation may also mean simply that the two traits are actually uncorrelated, regardless of the adequacy of their measurement. Because of this uncertainty of meaning, little interpretation is made in this volume concerning low and zero correlation coefficients. In view, furthermore, of the large probable errors attaching to these tetrachoric and biserial coefficients, we have arbitrarily chosen .20 as the lower

---

<sup>7</sup>Loc. cit.

limit of significance. Coefficients below this size are presented with little comment or interpretation.

#### Prejudicial Trends in the Data

While the effect of the factors of selection and instability of measurement on correlations is in general to reduce their magnitude toward zero, as we have pointed out in the preceding two sections, the effect of the two factors to be described in the next two sections—the factor of prejudices or biases in the data and the factor of varying completeness in the case information—is usually an increase in the size of obtained correlations or, in the case of negative correlations, a swing toward zero or toward the positive direction. Both of these problems arise from the subjectivity in the source of information based, as it is, so largely upon the personal beliefs or opinions of parents and examiners.

If there is a widespread belief among parents or staff members that two traits are associated or that one trait is a cause of another, this prejudicial influence may enlarge an obtained correlative coefficient between case-record notations of the two traits. For example, we note the relatively substantial correlations between enuresis and masturbation of .24 and .19 among boys and girls, respectively (see Table 97). Now it is entirely possible that these two traits are intrinsically correlated, but the possibility also exists that these coefficients also comprise a prejudicial effect arising from the fact that many parents believe, whether correctly or not, that masturbation actually causes bed-wetting, so that such parents of an enuretic child may search more diligently for evidences of masturbation, and, in view of its all-but-universal prevalence among children, are more likely to obtain these evidences than in the case of children whose parents have no special reason to suspect masturbation.

Such prejudicial or biased factors probably exist throughout our data. As a further example, one may be suspicious of our high correlations of bad companions (Table 82) with police arrest and the more conspicuous conduct problems, such as stealing, truancy from home, or heterosexual sex misconduct among girls. While clinical studies have indicated certainly that bad companions is an important causal factor in misbehavior, it is also probable that

our obtained coefficients have been somewhat enlarged by the additional bias arising from the well-known fact that parents tend to blame other people's children for leading their own children into trouble.

A further example will show how this prejudicial factor may enter into data obtained from the clinical examination. In our question of encephalitis, less than half of the cases were definitely so diagnosed, while the majority of cases were "questioned," i.e., the medical history or neurological signs alone were insufficient to establish the diagnosis. In such instances, then, the examining psychiatrist often makes a tentative diagnosis on the basis of the behavior manifestations themselves. Therefore, in our correlations of question of encephalitis (Table 117) with the very behavior traits commonly thought to arise as a result of this neuropathology, such as question of change of personality, emotional instability, "nervous," or temper, it is probable that the coefficients have been enlarged or influenced toward the direction of positiveness because of this prejudicial factor.

Let us turn to another defect in typical case-record notations, which tends to enlarge our coefficients or to influence their magnitude unduly toward the positive direction.

#### Differential Completeness of the Case-Record Information

While the recorders of the case-record information have made all reasonable effort to obtain information which would be adequate for the clinical treatment of our cases, one cannot assume that the extent of this information is uniform for all the 3,294 children of this study. Some parents are better acquainted with their children's activities than others and consequently possess more information to give to the recorders. Some parents have stricter standards of what constitutes undesirable behavior and are therefore prone to enumerate a longer inventory of personality and conduct problems than are parents with a more liberal and easy-going attitude toward their children's behavior. Of similar effect is the great variation among parents themselves in their actual treatment of their children. It is a matter of frequent observation that some parents actually evoke undesirable behavior reactions

in their children through unwise management, so that in such instances the child's behavior becomes largely an index of his parent's attitude and conduct. Furthermore, varying facility in the use of language may work against uniformity in the amount of case data obtained, e.g., a stupid or uneducated informant or an immigrant parent unproficient in the American language or a parent who is naturally bashful or taciturn, in contrast with university-bred mothers with active interest in child study.

For the sake of completeness, we might mention another possible source of nonuniformity in extent of case data, namely, varying willingness of the informants to co-operate in the giving of case information. This factor is probably not very serious in our material. Usually the parents have themselves been eager to obtain whatever aid the Institute can offer, since the home has been the party most affected. In any instances in which the parents were not frank with the staff, the case was usually discontinued before completion and consequently does not appear in this study.

As a counteracting influence, the history-taker, ordinarily a graduate psychiatric social worker or an apprentice working under her supervision—a person specially trained in the technique of interviewing—aims to elicit the essential facts concerning the child's life-history. She is an active getter of information and not a mere passive recorder. An outline is followed in the interview which covers the personality and conduct items commonly thought to be important in the explanation of the child's behavior. Among the 162 specific behavior and non-behavior items considered in this volume practically all are expressly called for in this history outline or else are clinical concepts which the examiners are very likely to investigate. For that reason it seems probable to the writer that the correlations covered in the present volume are not seriously distorted by the prejudicial or dilating effect of variability in the extent of data-recording. A comparison of the cases in which extensive social-service care was given with the cases in which only a routine examination was made showed that among the frequently appearing traits which are included in the present study most of the entries were made at the first visit.

---

<sup>8</sup> M. S. Mink and H. M. Adler, "A Suggested Outline for History-taking in Cases of Behavior Disorders in Children," Welfare Magazine, XVII (1926), 5-22.

New data elicited usually concerned such less frequently appearing trait notations as inability to get along with other children, self-indulgent attitude, overdependence on mother, lack of shame or concern over misdeeds, gluttony or overeating, cheating on school work and the like, which are not discussed in this volume. The personality-total and the conduct-total, i.e., the unweighted summation of the total number of personality and conduct problems reported for each child, are the only items in the present volume which would be seriously affected in respect to their correlation coefficients.

Let us illustrate the statistical mechanism by which the factor of varying fulness in the case-record information may magnify correlation coefficients artificially. Among the traits discussed in this study, seclusiveness is a more recondite and subjective entity than, for example, truancy from home or finicky food habits. The parent, then, who is discerning enough to mention seclusiveness is also more likely to be acute enough to note such other traits as daydreaming, sensitiveness, depressed spells, and the like, if they are present. On the other hand, a parent who is unable to think about behavior in fine terms would tend to omit any statement about either seclusiveness or sensitiveness, even if both traits are present in a child. In the one instance, therefore, a child may be noted as both seclusive and sensitive, while a hypothetical duplicate of that child may in the other instance receive neither notation. In a tetrachoric table made up of a group of such cases, therefore, too many individuals tend to be diverted into both the "noted-noted" cell and the "unnoted-unnoted" cell and too few into the other two cells. The effect on the correlation coefficient of this distortion in the fourfold table is an unwarranted thrust toward the positive direction, i.e., positive coefficients become artificially enlarged and negative coefficients become reduced toward zero.

The correlation coefficients in this volume will not be equally influenced by this factor. Some of the traits are relatively objective and observable, while others are of a more secretive or interpretive nature. It is probable that the correlation coefficients involving our personality-total and conduct-total were the most seriously influenced. While the items going to make up these totals were for the most part those which have been most

diligently inquired into by the history-taker and the clinic examiners, a substantial fraction were rarely appearing items which would be given by unusually well-informed or talkative informants.

There is, of course, no direct evidence that this factor of varying completeness of the case-record information was operative in our material. On the other hand, however, it seems significant to the writer that there are too many positive correlation coefficients, and too few negative ones.

#### Inadequate Defining and Ambiguous Grouping of Terms

A prime need is a terminology of trait names which are objectively definable, elementary, and, where possible, exclusive. Such an attainment seems to be next to hopeless.<sup>9</sup> In this study it was necessary to make a more or less arbitrary grouping of the descriptive terms as found in the case records. The actual statements by the informants include thousands of terms, many of which may be considered as redundant and synonymous. In indexing these many trait names an attempt was made to fix upon a system of nomenclature which conformed as far as possible to current usage in the literature and in the clinic routine.

The question arose at the outset as to the fineness or coarseness of the grouping of terms. It is necessary, on the one hand, to establish categories sufficiently fine so that the traits included therein are reasonably homogeneous. On the other hand, the categories should be broad enough to include all traits which are really homogeneous entities, regardless of the variation in terminology between different informants. In this research there was also the practical consideration that one should fix categories sufficiently broad, whenever permissible, to yield groups large enough for adequate statistical treatment. (After all, an original sample of 5,000 cases in this research has proved to be none too large.) In our inventorying, the aim was to choose as fine a classification as possible, to err on the side of an overfineness of

---

<sup>9</sup>Some of the difficulties have been discussed in Vol. I, Part II, and in the author's article, "On the Feasibility of Inventorying Children's Behavior Traits," Journal of Juvenile Research, XVI (1932), 32-39.

grouping rather than an overcoarseness. And in the light of subsequent examination of our data, it is probable that our standard of classification has attempted often to make impossibly fine distinctions, i. e., has attempted to place under separate rubrics many items which scarcely represent actual differences in behavior.<sup>10</sup> In some instances it seemed advisable to regroup some of the finer categories into larger classifications.<sup>11</sup>

The distortion in the bi-serial and tetrachoric correlation coefficients due to inaccurate defining of terms and to improper grouping of traits is under some conditions an unwarranted diminution of their values and under other circumstances an undue enlargement.

Too fine a classification means that what is essentially the same trait is incorrectly placed under two or more rubrics. In a bi-serial or tetrachoric tabulation, then, we have the anomalous situation that the same sort of cases are placed on both sides of the dichotomization. The effect will be to neutralize the force of any true underlying correlation, with the result of attenuation in the coefficient, i. e., a reduction toward zero.

If the categories are too coarse, i. e., if a given rubric is not a homogeneous affair but actually covers two or more dissimilar traits,<sup>12</sup> the effect on the correlation coefficients may be either an attenuation or a dilation. As an illustration, let us suppose that a too coarse category A comprises two somewhat dissimilar traits a and b, that is, two traits whose intercorrelation is not high. If trait a is substantially correlated with any outside trait X, while trait b is only negligibly correlated with trait X, the effect of combining a and b into trait A is in general a reduction in the correlation coefficient toward zero; i. e., when one throws together two or more groups of somewhat dissimilar cases into a composite and computes correlation coefficients on that composite, the usual result is a coefficient whose magnitude is

---

<sup>10</sup>Vol. I, Tables 1-13.

<sup>11</sup>Vol. I, Table 13.

<sup>12</sup>This problem has been discussed by Henry B. Elkind and Carl R. Doering, "The Application of Statistical Method to the Study of Mental Disease," American Journal of Psychiatry, VII (1928), 789-808, under the name of "mixed or hidden classification," which they describe as "the inclusion of known and unknown attributes in our classifications which are mixed in such proportions that they influence the result in which we are interested."

intermediate to the coefficients which would be obtained by treating each component trait separately.

In a few instances, however, the effect of clubbing together two or more groups of cases may be to elicit a higher correlation from the composite than from any of its components. Such may be the outcome when both a and b are substantially correlated with the outside trait X but are intercorrelated either negligibly or negatively with each other.

An empirical estimate of the effect of finer and coarser categories in our data may be made by comparing the correlations for the larger classifications indicated as "grouped, etc.," in the tables discussed in Part III. For example, grouped: depressed, etc. (Table 13) is a composite of depressed (Table 11) and unhappy (Table 12); grouped: dull, slow, etc. (Table 41), comprises slow, dull (Table 38), listless (Table 39), and lack of initiative (Table 40); grouped: "nervous," etc. (Table 48), comprises "nervous" (Table 45), restless (Table 46), irritable (Table 47), and changeable moods (Table 35); grouped: disobedient, etc. (Table 66), comprises disobedient (Table 61), incorrigible (Table 62), defiant (Table 63), stubborn (Table 64), and contrary (Table 65); grouped: fighting, etc. (Table 73), comprises fighting (Table 69), quarrelsome (Table 70), violence (Table 71), and threatening violence (Table 72); grouped: temper, etc. (Table 78), comprises temper tantrums (Table 76), temper display (Table 77), and irritable (Table 47); and grouped: lack of interest in school, etc. (Table 93), comprises lack of interest in school (Table 91) and inattentive in school (Table 92). A comparison of the corresponding correlations in the "grouped" categories with those in the more specialized categories shows that the broader categories as a rule yield coefficients which are either intermediate in size or else slightly larger than those for the component categories. It seems probable to the writer from such a comparison that the classifications of behavior attempted in this study have been too fine rather than too coarse.

In deciding upon how restricted a classification one should employ in studies of this kind, it is probable that we must rely chiefly upon our subjective interpretation of the meanings of these trait names, in spite of our desire for refined objective methods of discrimination.

There are, however, two statistical devices which will assist one in making decisions in specific instance. One method consists of comparing the correlation coefficients of each trait against a large number of "outside" traits or conditions. If the two traits are found to show important divergences in their correlation with other traits, then this procedure establishes the fact with certainty that the two traits in question should be considered separate entities. On the other hand, if the two traits show generally similar outside correlations, this criterion is not in practice so serviceable. If we could be sure that our outside traits or conditions included all the important ones conceivable, then it would be possible to conclude that these two traits were for all practical purposes identical. But the question will always arise whether any series has not failed to include certain other important traits or facts which would have shown divergent correlations. Therefore, if the purpose is to eliminate a category on the ground that it so closely resembles another accepted category, this procedure does not by itself constitute a decisive criterion, but it possesses some utility in reinforcing one's evidence obtained from other sources.

Some illustrations from our material will make this method clear. We have set up two similar and overlapping rubrics, temper tantrums and temper display. The question arises whether these are different enough to justify separate treatment. Temper tantrums in their "classic" form involve such bizarre behavior as banging one's head against a wall or floor, biting one's own hands, or running around in circles, while in temper display the behavior usually consists in an excessive emotional discharge such as hitting or swearing, which bears more directly upon the apparent purpose of the child. On the other hand, it can be urged that both are expressions of the same desire, i.e., to coerce others into yielding to the child's wishes and that the overt differences which I have just mentioned are really superficial. To test this point, the correlations of the traits against a list of about 120 other traits or conditions (mental, emotional, physical, educational, familial, and social) were compared. (These coefficients were chiefly Pearson's tetrachoric-r's with chronological age "partialled" out.) The product-moment correlation of these coefficients was  $.66 \pm .03$ . Now this intercolumnar correlation is so low in comparison with others in our material that it seems safe to conclude that these two notations should be placed under separate categories.

Another example in our material will illustrate the less decisive alternative. The question arose whether the two notations bad companions and running with a gang should be considered as separate categories. Running with a gang according to our definition implies bad companions, the main difference being that a gang involves some degree of organization or duration while bad companions may be a more sporadic and transient affair. The intercolumnar correlation was found to be  $.81 \pm .02$ . In this instance the evidence of such a computation suggests that the latter pair, bad companions and running with a gang, are definitely more similar than the former pair, temper tantrums and temper display. Whether this intercolumnar correlation of  $.81$  is high enough to warrant one's grouping both notations into one category is another question. If a brief

list is desired, the correlation may be considered sufficiently high to justify the elimination of a separate rubric, but in view of the persistent belief that the influence of youthful city gang associations tends to continue beyond the eighteen-year age limit of our group<sup>13</sup> it was concluded that important differences may exist which were not adequately represented in our series of 120 outside traits.

The other statistical device consists in comparing the outside correlations for the traits taken separately with those for a coarser grouping comprising all the similar notations. If the coarser grouping should produce lower correlation coefficients than the more restricted notations considered separately, the coarser grouping should be avoided because such a result probably means that heterogeneous traits have been included in that coarser grouping. If, on the other hand, the coarser grouping yields generally larger correlation coefficients than the finer grouping, this evidence is to some extent in favor of the coarser grouping. This does not constitute a decisive criterion, however, since a compositing of traits in this manner may approximate the outcome of Yulean multiple correlation in which the addition of fresh variables tends to increase the multiple correlation coefficient and never to decrease it.

An example in our material will illustrate the procedure. Among the five categories disobedience, defiant attitude, incorrigibility, contrariness, and stubbornness the question arose whether there may be some redundancy. A broader grouping was set up to include all cases showing any one of these five traits, and a series of 117 outside correlations were computed. The broader grouping, in the main, yielded larger coefficients, as one might expect, but there were marked differences among the five traits. The specific notation contrariness (or negativism) gave thirty-three coefficients higher than those for the composite category out of a total of 117 coefficients and therefore should be considered as a separate category. Incorrigibility and stubbornness similarly gave twenty-six and twenty-five coefficients, respectively, higher than those for the composite category, and therefore should be retained as separate categories. Disobedience and defiant attitude, on the other hand, showed only seventeen coefficients each higher than those for the composite category, and therefore became candidates for elimination as far as this criterion is concerned. This analysis of this troublesome group of overlapping notations is, of course, very incomplete. An additional refinement would consist in repeating the process of compositing after eliminating the more obviously independent traits one by one. The possibility of applying some form of the Spearman common-factor techniques to this problem is also suggested.<sup>14</sup>

---

<sup>13</sup>F. M. Thrasher, The Gang: A Study of 1,313 Gangs in Chicago (Chicago: University of Chicago Press, 1927). Pp. xxi + 571.

<sup>14</sup>Quoted from the author's article, "On the Feasibility of Inventorying Children's Behavior Traits," op. cit., pp. 32-39.

An overlapping in the meaning of trait names also presented a difficulty in the original indexing of the case material and a distortion in certain correlation coefficients. For example, we have made separate categories for depressed, discouraged attitude, spells of depression or discouragement, on the one hand, and unhappy or discontented attitude or appearance, on the other. These two traits are very similar and may often be used synonymously in the original data. In cases in which both notations are applicable both should be used. But often it is probable that an explicit mention of the one by the informant tends to exclude mention of the other apparently redundant trait name. Consequently, the tetrachoric tabulation concerning the correlation between two such overlapping trait notations will have too few entries in the "noted-noted" cell, e.g., in the cell containing the children in whom both "depressed" and "unhappy" should be entered, and as a consequence the correlation coefficient shows too low a value. In Tables 6-130 there are many instances in which the correlations between similar and probably overlapping trait names are too low to be credible: the correlations between depressed and unhappy (Table 11 or Table 12) were  $.40 \pm .05$  for boys and  $.33 \pm .08$  for girls; those between seclusive and repressed (Table 31 or Table 32) were  $.16$  and  $.40 \pm .07$ ; those between egocentric and selfish (Table 51 or Table 52) were  $.21 \pm .04$  and  $.45 \pm .05$ ; those between disobedient and stubborn (Table 61 or Table 64) were  $.30 \pm .03$  and  $.37 \pm .04$ ; and those between lack of interest in school and inattentiveness in school (Table 91 or Table 92) were  $.06$  and  $.28 \pm .06$ . The data for the intercorrelation of temper tantrums and temper display (Table 76 or Table 77) appeared from inspection to be so unsatisfactory that the coefficients were not reproduced here. The correlation coefficients between any two such overlapping trait notations as these in our tables, therefore, are probably too low to be representative of the true relationship existing between those traits.

In short, in such material as ours, we do not have unadulterated or simon-pure, objectively determined categories, so in any series of correlation coefficients we are really obtaining some sort of "team" or "sums-and-differences" correlations in which the intercorrelations and weightings of the component elements are obscure. The effect, therefore, of inadequate defining and classifi-

cation of trait names upon our correlation coefficients may be in some instances a deceptive diminution, in other instances a deceptive magnification, and in some instances—let us hope—a negligible influence.

#### The Use of Categorical Trait Names instead of Measured Variates

The discussion of the bi-serial and tetrachoric methods of correlation in chapter iii<sup>15</sup> has indicated the inferiority of categorical data in respect to correlational methodology. The next few paragraphs will indicate how this deficiency obscures the interpretation of correlation coefficients based upon such dichotomized data.

The ideal statistical material should be in measured and continuous or graduated units, since such data permit drawing up a scatter diagram in which one can observe in detail the statistical behavior of variates in whose correlation we are interested. For example, we may wish to know such factors as normality of distribution, linearity of regression, kurtosis, scedasticity, and whether there are any unusual concentrations or any lacunae in any portions of the distribution. In a bi-serial tabulation one of the traits is compressed into a "noted" and "not noted" dichotomization and in a tetrachoric tabulation both variates are so compressed that such refined information is not ascertainable.

The most complete and meaningful representation of the correlation between two traits is the actual scatter diagram. The product-moment coefficient is a secondary symbol to bring out in a concise and comparative manner the amount of the relationship. Since scatter diagrams are space-filling affairs, they are seldom presented in publication, but the correlation coefficients are employed to represent in economical fashion the essence of the scatter diagram. While the product-moment coefficient is thus a substitute device, the bi-serial and tetrachoric coefficients become in turn only a makeshift for the standard product-moment coefficient. The only justification for the use of such inadequate methods of correlation in research is the lack of satisfactory

---

<sup>15</sup> Esp. pp. 14-19.

quantitative data permitting more complete and precise treatment, and the results obtained from such correlation methods should be regarded as only tentative and exploratory.

The obscurity in the form of correlations obtained from the use of categorical trait names instead of measured variates makes difficult the interpretation of certain apparently inconsistent correlations which will be noticed in Tables 6-130. These are among the correlations obtained from presumably "opposite" traits,<sup>16</sup> e.g., unpopular (Table 27) and popular (Table 28), over-suggestible (Table 42) and stubborn (Table 64), slovenly (Table 89) and clean (Table 90), and "leader" (Table 107) and "follower" (Table 108). Here we occasionally find that both members of a pair of "opposite" traits correlate positively and substantially with the same "outside" trait. For example, "leader" correlates  $.26 \pm .04$  with running with a gang among boys (Table 83), while "follower" correlates  $.21 \pm .04$  with the same notation. Now one explanation may lie in a possible curvilinearity of regression of running with a gang on the combined trait "leader-follower," i.e., boys who participate in gang activities tend to be either leaders or followers (since a gang must have some of each kind in order to maintain its organization), while boys who are neither leaders nor followers do not tend to become implicated in gang activities. Another possible explanation may be that these and other "opposites" are not really the opposite poles of a single underlying trait. It may be that the true antithesis of "leader" is not "follower," but "indifference," i.e., the incapacity or unwillingness either to lead or to follow. Thus it may be that the same individuals who under one situation are leaders may under other conditions take the role of follower, while the true "opposite" is represented by the child who neither leads nor follows.

#### Inadequate Representation of Desirable and Indifferent Traits in Case Data

The examination in typical children's behavior clinics tends to cover the undesirable or "ominous" personality and conduct

---

<sup>16</sup>See I, 134-35 and this volume, final paragraphs of chaps. xx, xxv, xlv, and liii.

traits with considerable thoroughness. Much less attention is given the desirable and presumably "indifferent" traits. This results in an under-representation of the "assets" in the child's behavior makeup in comparison with the "liabilities."

Among the 96 behavior traits specially studied in this volume, 90 may be considered as unquestionably undesirable, while only 6 desirable or presumably indifferent traits (popular, clean, sex denied entirely, "leader," "follower," and attractive manner) appeared to have been inquired into diligently enough to warrant inclusion in our study.

This inadequate representation of the desirable and indifferent traits cannot affect the individual correlation coefficients presented in this study. But it precludes the possibility of interpreting a series of correlations of one trait with all the other frequently noted traits selected for this study in any comprehensive manner. As they stand, the correlations present only one side of the picture—the relation of certain traits to undesirable traits. In an exploratory study such as the present one it would have been very meaningful to have had in one series the correlations with all other traits of frequent occurrence, in order to obtain a more comprehensive view of the significance of traits in the light of their correlations with other traits.

### Summary and Discussion

The points discussed in this chapter may be summarized as follows:

1. The selective factors operative in the admission of children to clinic examination tend in general toward a restriction of range and therefore toward an attenuation in the correlation coefficients or a reduction toward zero.

2. The factors of unreliability and subjectivity, which are undoubtedly very considerable in our material, tend likewise to reduce the correlations toward zero. Unfortunately, there appeared to be no feasible method of obtaining a measure of these factors, whereby one could estimate the theoretical correlation which would be found to exist under conditions of perfect reliability or objectivity.

3. The effect of prejudicial or biased trends in the data,

i.e., the preconceived notions of the parents or staff examiners that certain traits either do or do not occur together, is usually to swing the correlation toward the positive direction. Positive correlations are thus enlarged, negative correlations are reduced, and low negative correlations may at times be distorted into low positive correlations.

4. The effect of variations in the completeness of the case-record information is likewise a swing toward the positive direction.

5. The effect of an inadequate defining or ambiguous grouping of terms upon correlations is usually an attenuation or reduction toward zero but under some circumstances may be an increase in the size of the correlation.

6. The use of categorical trait names instead of measured variates need not distort the value of the correlation coefficient if the distribution of the trait underlying the categorical notation approaches sufficiently to the normal or Gaussian. The serious defect in categorical notations is that the actual form of the distribution is so obscured that one is unable to ascertain its form.

7. The inadequate representation of desirable and presumably indifferent traits in our case data does not have any effect upon the individual correlation coefficients but precludes the possibility of obtaining a comprehensive view of the meaning of a trait in terms of its correlations with other traits.

We see, then, that in typical case-record data there are many uncontrolled factors, some of which magnify the obtained correlation coefficient, while others diminish it. These factors tend to neutralize to some extent the distorting effect each has upon the other. But one cannot estimate whether the net result still leaves the coefficient too high or too low. For that reason we are allowing a considerable margin of safety in our interpretation of the correlations in this volume by confining the discussion only to coefficients greater than .20. This does not imply that correlations below this size are without meaning. Many of the underlying relationships between traits which must be taken into consideration in the actual care of children presenting behavior difficulties are probably no larger than this. If the results of a research are intended to be applied in a practical manner in some

highly organized or collectivized society in which millions of children would be affected, statistically significant coefficients smaller than .20 would be of definite social importance. But since we cannot be more sure of our data, it is better to jettison this portion of our material and confine our attention to correlations well above zero.

This chapter has been intended as a critique of clinical case records as research material. Workers have long been aware of their many inadequacies, and this chapter has attempted to analyze in greater detail the difficulties and to point out how they function in actual studies.

The shortcomings of such data will be equally operative in other research methodologies, it should be pointed out, and not only in studies employing the method of Pearsonian correlation. Such devices as group differences, contingency, the probability methods, or graphical representation require fewer assumptions and make less claim to refinement of procedure, but the same distorting influences are at work. The advantage of refined correlational methods, even though the data are defective, is that the effect of such deficiencies becomes more obvious.

It is unnecessary and injurious, however, to become so obsessed with the presumptive defects of case data as to conclude that they are valueless for research purposes. To the writer the findings obtained from our material have enough plausibility to reassure him that this sort of material has a large field of utility for research needs under the proper restrictions of interpretation. Greater use should be made of the case-record material which accumulates rapidly in all behavior clinics. Such data do not permit precise, unequivocal, controlled conditions comparable to the classic researches in the older physical and biological sciences. Researchers in the social sciences must necessarily employ to a lesser extent the adequately standardized and objective data because at present few of the complex functions of gross human behavior have been reduced to satisfactory measurement. The social scientist must be ready for the present to work with data admittedly inadequate and must couch much of his interpretation in terms of trends, probabilities, multiple causal factors, correlations, and the like. The correlation coefficients presented in this volume, then, must not be considered as final psychologic,

sociologic, or biometric constants but must be regarded as provisional, until future studies can be made under improved conditions of selection and improved methods of gathering and recording such data.

Any betterment in the technique of constructing case records will necessarily enhance research results obtained therefrom. Improvement may take place in two respects.

1. More complete and more verified information for case records will meet with the enthusiastic approval of research workers. But from the standpoint of clinic routine there are important limitations to the amount of effort and time which can be spent on each case: first, the available staff personnel in comparison with "case load" and, second, the amount of time which can be required of an informant. A behavior clinic supported from state or municipal funds or by "community chests" is expected to take care of all appropriate cases brought to it, and this demand for service often relegates the purely research aspects to a position of secondary importance. It is also desirable to complete the interview with a parent within one sitting or with as few subsequent sittings as possible. In clinics endowed for the specific purpose of research or for intensive work upon a relatively small number of cases the possibility of accumulating fuller case data is much greater. Actually there has been a tendency for case records to contain more and more material, owing to the fact that, as our knowledge of children's behavior has increased, we have realized more and more that the causal factors are numerous and complex.

The use of a formal printed schedule or questionnaire would automatically insure uniformity and a certain degree of completeness of information. But the objections are many. They are likely to take away the spontaneity and rapport of the interviewing process. They may tend to elicit superficial judgments as to the presence or absence of a trait. They may slur over any special items which are of particular importance in the individual case. They do not enable the interviewer to make adequate emphasis of conspicuous elements in the situation. They would be uneconomical of time in actual clinic practice, since large sections of such a universalized schedule would comprise items not applicable to the individual case. Probably the best use of a formal schedule is in a special study of a specific problem covering a restricted series

of cases.

2. The second desideratum is an increase in measurement devices. These, however, accumulate slowly. Many worthy attempts have been made to derive home-rating and neighborhood-rating scales, scales for evaluating parental occupation, for evaluating the occupational capacities of children, and for measuring various personality traits. It seems probable to the writer that some of these have been developed well beyond the experimental stage and already deserve inclusion in the clinic routine. As a matter of fact, however, few of them have at the time of writing attained sufficient credence to place them there. In actual practice the preference still remains on the side of subjective estimates, whether rightly or wrongly.

## CHAPTER V

### THE BEHAVIOR TRAITS DISCUSSED IN THIS VOLUME

As a convenience in listing the items discussed in this volume, a division of them may be made into three groups. In the accompanying tables these items are listed, together with their frequencies among 2,113 boys and 1,181 girls. For example (Table 1), police arrest was noted in 457 cases among 2,113 boys and in 179 cases among 1,181 girls. The wording in which these are given is a concise one intended to save space in the large number of subsequent tables. A more complete and exact description is given at the head of each section in which are collected the coefficients concerning a given trait or condition.

The 111 items in Table 1 were employed in correlations with all items in Tables 1 and 3. These are chiefly the often noted personality and conduct problems in our case data, together with a few other traits or conditions. These coefficients will be found on later pages in Parts II and III.

TABLE 1  
TRAITS FOR WHICH CORRELATIONS WITH ALL TRAITS  
IN TABLES 1 AND 3 WERE COMPUTED

	Frequencies	
	Boys	Girls
Personality-total.....	(2,113)	(1,181)
Conduct-total.....	(2,113)	(1,181)
Police arrest.....	457	179
Chronological age.....	(2,113)	(1,181)
Intelligence quotient.....	(2,113)	(1,181)
Depressed.....	149	73
Unhappy.....	95	64
Grouped: depressed, etc.....	219	125
Crying spells.....	473	297
Sensitive (general).....	163	92
Sensitive over specific fact.....	322	156
Worry over specific fact.....	100	40
Grouped: sensitive or worrisome, etc...	490	255

## CHILDREN'S BEHAVIOR PROBLEMS

TABLE 1—Continued

	Frequencies

Retardation in school.....	878	474
Poor work in school.....	632	319
Exclusion from school.....	204	71
Attractive manner.....	307	165
Stuttering.....	83	.....

## CHILDREN'S BEHAVIOR PROBLEMS

The 36 items in Table 2 were employed only in correlations with personality-total, conduct-total, police arrest, chronological age, and intelligence quotient (Tables 6-10). They are similar in nature to the items in Table 1 but of less frequent occurrence, so that it was felt that extensive statistical analysis was not warranted.

TABLE 2

TRAITS FOR WHICH ONLY THE CORRELATIONS WITH  
PERSONALITY-TOTAL, CONDUCT-TOTAL, POLICE  
ARREST, CHRONOLOGICAL AGE, AND INTEL-  
LIGENCE QUOTIENT WERE COMPUTED

	Frequencies	
	Boys	Girls
Dementia praecox.....	50	.....
Incipient psychosis.....	41	.....
Psychopathic personality.....	91	41
"Night terrors".....	62	34
Talking to self without apparent reason.....	46	25
Lack of affection.....	50	.....
Tiring easily.....	69	38
"Sugar hunger".....	72	.....
Resentful attitude.....	78	51
Failure to adjust in foster-home.....	50	50
Disturbing influence in home.....	78	48
Irregular employment record.....	72	39
Stealing an automobile.....	58	.....
Robbing a building, home, etc.....	70	.....
Truancy from institution.....	123	.....
Swearing at mother, teacher, etc.....	57	.....
Bad language.....	83	40
Obscene language.....	90	.....
Bullying.....	75	.....
Cruelty to younger children.....	71	.....
Cruelty to animals.....	53	.....
Fire-setting.....	44	.....
Sneaky.....	70	37
Gambling.....	51	.....
Begging.....	68	.....
Gluttony.....	81	35
Sex attack on opposite sex.....	60	.....
"Annoying" girls.....	69	.....
Mutual masturbation (same sex).....	80	.....
Homosexual (same age).....	73	.....
Passive pederasty.....	49	.....
Exhibitionism.....	46	.....
Bowel incontinence.....	50	19
Thumb-sucking.....	58	40
Illegitimate parentage.....	65	45
Immoral sister.....	53	60

The 14 items in Table 3 were employed only in correlations with the items in Table 1. The coefficients will be found in Tables 6-130. These consist in miscellaneous, frequently noted physical, educational, and familial conditions which would not be considered as behavior problems or difficulties. They scarcely belong logically with the other traits discussed in these pages but were included in this volume for comparative purposes.

TABLE 3

MISCELLANEOUS TRAITS OR CONDITIONS FOR WHICH  
CORRELATIONS ONLY WITH THE ITEMS  
OF TABLE 1 WERE COMPUTED

	Frequencies	
	Boys	Girls
Underweight.....	349	193
Headaches.....	118	86
Former convulsions.....	155	54
Neurological defect.....	191	120
Question of encephalitis.....	70	37
Lues.....	106	86
Speech defect.....	180	92
Vocational guidance.....	238	169
Irregular attendance at school.....	162	102
Feeble-minded sibling.....	110	103
Brother in penal detention.....	137	103
Vicious home conditions.....	85	68
Immoral home conditions.....	107	101
Discord between parents.....	525	285

The 162 traits discussed in this volume were selected from the total number of traits listed in Volume I, Tables 1-13, on the basis of frequency of occurrence among our cases rather than because of any imputed special significance.

## CHAPTER VI

### THE EXPLORATORY AND THE AD HOC APPROACHES IN RESEARCH

The choice of trait notations indicates the exploratory character of this study. On the basis of sampling, consisting of 5,000 cases, it was found that the 162 notations described in the preceding chapter occurred often enough to warrant a systematic correlational treatment. Only to a slight extent did any a priori considerations of intrinsic importance or interest enter into the selection of these 162 trait notations. If our sampling had consisted of 10,000 cases or 25,000 cases instead of 5,000, the number of behavior items studied would have been correspondingly larger.

The reader will note the absence of any specific hypothesis guiding this study, unless we consider the principle of multiple etiology itself to be a hypothesis, i.e., the principle that the causes of children's behavior problems are numerous and of varying degrees of potency from child to child and in the mass (see pp. 3-4). In planning this research the writer has sought to avoid the espousing of any special theories concerning either interrelations or causality, though there would be no lack of excellent theories to choose from if it were so desired. It was felt that the conditions peculiar to this research, i.e., an extensive provision of card-sorting and calculating machinery and clerical assistance at the outset of the work enabled one to plan on a comprehensive factual investigation into many possible components of behavior traits rather than to set up an intensive examination of any specific question which one might set. To have adopted some definite "working hypothesis" would have restricted unnecessarily the scope of the inquiry, in addition to exposing one to the ever present danger that such a priori attitudes may interfere with an impartial and unprejudiced appreciation of the actual facts present in the data.

Another practical reason for adopting an empirical and

exploratory approach in this inquiry is that the major part of the case data had already been gathered and little additional information concerning our children could be obtained except with considerable inconvenience and expense. While the original case material has attempted to be fairly complete, often comprising over a hundred typed pages of information concerning a case, the items covered usually varied from child to child according to the individual requirements for diagnosis and recommendations. For that reason seldom were the data sufficiently uniform or complete over a large series of cases to afford the opportunity of framing a precise crucial research concerning a specific relationship.

In the research designed for an intensive or conclusive study of a clear-cut theorem, on the other hand, the worker usually desires to gather his data ad hoc, i.e., for the special purposes of his problem. He typically formulates a working hypothesis and then seeks only the data which presumably are pertinent to that hypothesis and ignores any data which appear irrelevant. This distinction between the two modes of research, which may be designated as the ad hoc approach and the exploratory or empirical approach, is briefly stated by Wilder D. Bancroft:

The first of the two general methods of research is that in which one first gets one's working hypothesis and then accumulates data to test it. The second general method is that in which one accumulates data until the general theory underlying them becomes obvious.<sup>1</sup>

The slogan of the former is "First get your working hypotheses," he says, the plural being used advisedly because it is always better to have several working hypotheses if possible. The slogan of the latter is "First get your facts."

The ad hoc study is especially appropriate in the more mature fields of science, as in the physical and medical sciences, where there already exists an abundance of well-established knowledge and where there are many ramifications in which the "next step" to be taken is obvious. The desideratum here is a final and unequivocal answer to some well-defined query.

In an ad hoc study the hypothesis varies in specificity. In some instances the researcher may have a "hunch" or supposition that a certain relationship exists. This may at times come a priori

---

<sup>1</sup>"The Methods of Research," Rice Institute Pamphlet, XV (1928), 171-72.

from speculation or reading but is more likely to be based upon some fragmentary research or upon less formal observation of the phenomena within a field with which the worker is familiar. He then sets up a research or series of researches to test the truth of this thesis. If his hunch is not verified by the test, the worker may feel that his work is "unsuccessful" (though actually it may yield many valuable by-products if he is shrewd enough to see them). Such unitary researches require considerable imagination or "genius" on the part of the worker. If we can credit the many semipopular accounts of what may be termed the "classical" researches in the progress of science, many examples of this procedure will be readily recalled by the reader. In other instances the researcher may allow himself a greater latitude. He may set his research to ascertain the answer to a certain question according to this formula: Is the given relationship positive, negative, or indifferent, or, to speak in terms of coefficiential correlation, what is the sign and amount of this relationship? Regardless of what the answer turns out to be, the research, if properly planned and carried out, is successful. Examples are numerous, especially in the dissertations of advanced students and in the current scientific journals: What is the effect of adenoids and diseased tonsils on children's intelligence or Is the "only child" more likely to manifest personality difficulties than the child with siblings? Or in other instances the research may permit of a less strictly defined answer, e.g., how do foundling children turn out? In examples such as this the approach may be considered as either ad hoc or exploratory, and there is no need for attempting to force such a borderline instance into a rigid category.

In the typical exploratory or empirical research the hypothesis guiding the investigation is couched in general, noncommittal terms, which may often seem lacking in clarity to the reader. The worker gathers a wide range of material and tries to include everything which may have a bearing upon his field of study and does not attempt to justify in detail every item in his data schedule. He depends chiefly upon his martialing of the data to bring to light any underlying relationships or principles of which he may or may not have been cognizant in advance of actual trial. In other words, he relies more upon his instruments or research procedures to elicit the truth than upon his own previous insight into

the problems which he is studying.

An exploratory research is especially appropriate in a relatively young field of scientific inquiry, partly because here there is little experimentally determined groundwork upon which to base a more specific hypothesis and partly because in such virgin soil whatever the researcher does is likely to yield valuable new information. Such studies are likely to raise more questions, however, than they answer. It is safe to say that in the early study of anatomy, physiology, and medicine and in the identification of disease processes, such as "Addison's disease," the approach was exploratory in the main, partly because at that time the techniques of research had not been brought to the more or less formal science which we have at the present day.

For similar reasons an important new discovery or invention in research methodology will bring about a large amount of empirical investigation. The query naturally arises as to whether the new techniques are able to throw new light upon the persistent problems within a science. For example, the discovery of serum therapy in medicine initiated a mass of largely exploratory experimentation to ascertain its usefulness in almost every important disease. Other examples may be cited: the large amount of statistical investigation in the social and biological sciences following upon Karl Pearson's devising of correlation methods or, at this time of writing, the numerous "common-factor" studies in psychology and education following upon Spearman's and Thurstone's devising of new techniques.

The two approaches differ in the location of the "hunch"<sup>2</sup> or "leap of the imagination over gaps in the evidence" to the discovery of the generalization underlying the data. In the exploratory inquiry this comes late in the process. It ordinarily comes a posteriori as a result of surveying the data and the indications brought out by the manipulations thereof. The worker would prefer an objective procedure in which the conclusions become self-evident, but often the interpretation of the underlying trends is a matter

---

<sup>2</sup>For an interesting questionnaire study of the circumstances under which the "scientific hunch" occurs, based upon the replies from 232 "scientists of admitted leadership," see Washington Platt and Ross A. Baker, "The Relation of the Scientific 'Hunch' to Research," Journal of Chemical Education, VIII (1931), 1969-2002.

of considerable insight and scientific imagination, if the investigator aims at something more than a mere enumeration of research "findings." In the ad hoc procedure, on the other hand, the hunch or "working hypothesis" precedes and determines the program of the study. This hypothesis, as we have said, is probably obtained from a tentative or inadequately supported conclusion from earlier studies made by the worker or by others or may at times appear to be a sort of "happy inspiration" obtained largely from a priori speculation.

While this brief chapter has been devoted to a differentiation of these two approaches in so far as it may serve to explain the exploratory aims of the present study, a caution is probably necessary lest the contrast be pushed too far. The researcher himself should, of course, be fully aware of the distinction in planning and carrying out his work and especially in preparing his report for publication. But in actual work it is probable that almost every empirical study has been planned with some anticipation of the sort of outcome which may be expected and that most ad hoc researches have been outlined to permit a degree of flexibility in order to be on the watch for the almost inevitable "unexpected" in research. How would one describe Charles Goring's classic, The English Convict?<sup>3</sup> From the introductory pages one may surmise that much of his original plan was specifically to submit to actual test Lombroso's belief in the existence of a differentiable "criminal type"; but in the body of his report he follows more the form of an exploratory research, with conclusions which would scarcely have been expected in advance of actual analysis of his data.

In a comprehensive research program involving a laboratory staff of several workers, both approaches have their usefulness, according to which portion of the undertaking each worker is concerned with. In such situations the course of a research program is a continuous process. Exploratory or empirical studies are undertaken to uncover new leads or clues, which will serve as working hypotheses for the more final and decisive ad hoc studies.

The interdependence of the two modes is thus best explained as a developmental schema. In a relatively new field of study or

---

<sup>3</sup>The English Convict: A Statistical Study (London: H.M. Stationery Office, 1913). Pp. 440.

when a new instrument of research is to be applied, the exploratory procedure is the favored one. In a more developed field, in which the fundamental principles are pretty well known and the desire is to close up certain "loose ends" in our knowledge, the ad hoc procedure is naturally to be preferred. The empirical investigation is thus a more primitive and contributing project, usually following a somewhat routine course. The ad hoc aims at a final conclusive answer and usually offers a greater opportunity for the researcher's personal insight and resourcefulness. The well-wrought ad hoc research follows as a model the familiar type of theorem in elementary geometry, in which the student demonstrates not only that if the given conditions are fulfilled the proposition is true but also that unless all the essential conditions are present the proposition is not necessarily true.

Each method is subject to its own misuse. This is, of course, due not so much to any fault in either method as to the limitations of the researcher himself.

The empirical worker may rely too exclusively upon his objective manipulation of the data to elicit automatically any unforeseen generalizations. He may forget that the ultimate interpretation of meaning is a subjective process and that his objective methods are after all merely the instrumentation. His report may become a mere fact-finding survey, useful enough in itself, which misses, however, its opportunities for original discovery of new principles. It may at times degenerate into routine presenting of an undigested and indigestible mass of data, from which neither the researcher himself nor the reader may gain much useful knowledge.

The ad hoc method, in contrast, is peculiarly liable to the defects of oversubjectivity. The worker may so restrict his attention to his guiding query that he may overlook valuable implications or by-products of his study. Often the by-product may be more important than the main quest itself. At worst, the ad hoc research may lapse into a strongly prejudicial effort merely to prove one's hypothesis. One must at times marvel at the regularity with which the researches undertaken in certain laboratories, closely identified with definite beliefs or opinions, all seem to come out with results in conformity with that point of view, even though there may be other equally competent laboratories

with a contrary point of view, whose researches likewise all seem to eventuate in conformity with the contrary point of view.

To contrast the two approaches from the standpoint of "efficiency" or convenience is a consideration of secondary importance, since the choice of method must be guided mainly by the requirements of the data and the research situation, as we have attempted to show in the preceding pages. The prime utility of the ad hoc study is in affording the final answer to some specific question, while the utility of the empirical survey lies in disclosing new facts or queries in a relatively unexplored field. Because of its adaptability to problems of restricted scope, the ad hoc method is greatly favored by students, teachers, and other workers who are limited in time and resources. The exploratory researches usually necessitate a more formidable plan of work and, as a consequence, are likely to be undertaken only in laboratories or institutes able to provide sufficient equipment and personnel.

The foregoing pages have attempted to make clear why the writer has so definitely chosen the exploratory approach instead of the more conclusive ad hoc approach. The reasons may be summarized as follows: (1) Children's behavior problems comprise a field of study almost untouched by formal researches. (2) Consequently, there is not a large amount of experimentally established groundwork upon which to base specific ad hoc researches. (3) The Pearson correlation methods have been utilized to a relatively small degree in this field, which is so well adapted to a systematic correlational analysis. (4) The data were already gathered, and only to a small extent could they be amplified to satisfy the needs of the more final and crucial ad hoc studies. (5) The original plans for this research project were sufficiently elaborate to permit a comprehensive exploratory survey of the many factors which are presumably of importance in the field.

## CHAPTER VII

### EXPLANATION AND INTERPRETATION OF THE TABLES

The remaining chapters of this book are filled with tables of correlation coefficients. For each of the 125 traits listed in Tables 1 and 3 of chapter v there is such a table.

#### Construction of the Tables

In order to facilitate the reader's comprehension of the trends shown in the 125 tables of correlations, these coefficients have been arranged as far as possible in descending order of magnitude or, more strictly, from high positive values through zero to increasingly negative values, according to the boys' correlations.

Within each table the correlations for personality-total, conduct-total, and police arrest are placed first because of their peculiar interest in this study.

Under the subheading "Larger Correlations (Positive)" are listed in descending order of magnitude the positive boys' correlations down through .20. Since the girls' coefficients do not necessarily follow the boys' ranking, their position is indicated by the rank order in parentheses. For example, in Table 6, personality-total (p. 89), the symbol "(1)" after violence means that  $.64 \pm .03$  is the largest positive correlation obtained among girls, "(2)" means that  $.61 \pm .03$  is the second largest positive correlation among girls, "(3-4)" means that there were two coefficients of .59 and that these take the third and fourth places in order of decreasing magnitude, "(16-19)" means that there were four coefficients of .50, and that they fell in the sixteenth, seventeenth, eighteenth, and nineteenth places in order of decreasing magnitude, and so on. Following these are listed the girls' coefficients of positive values of .20 or above, for which the corresponding correlations for the boys are less than  $\pm .20$ .

Under the subheading "Larger Correlations (Negative)" are

placed negative coefficients of  $-.20$  or greater. These are similarly arranged in descending order of negativeness, first, according to the boys and, following these, according to the girls.

The "Not Calculable (N.C.)" are placed next, because, in meaning, these correlations belong with the negative. (In these instances the frequency for the "noted-noted" cell of the tetrachoric tabulation was 0, and a tetrachoric correlation coefficient on such a tabulation is unobtainable.) For example, in Table 11, depressed (p. 136), none of the children noted as depressed had a notation of feeble-minded sibling. The association between these two notations, therefore, would be considered as negative.

Under the subheading "Other Correlations (Positive to Negative)" are placed all other coefficients with values falling between  $+0.19$  and  $-0.19$ . They are arranged according to the boys' correlations in descending order from  $0.19$  down through 0, and then in increasing order of negativeness up through  $-0.19$ .

The "Omitted" correlations are placed at the end of each table. These correlations were not computed, either because for some technical reason such a coefficient would be meaningless (as in Table 13, grouped: depressed, etc. [p. 144], where it would be absurd to correlate a pooled category against the component items of that pool) or because for some reason the indexing of a certain pair of items is so unsatisfactory that a coefficient would be greatly misleading (as, in Table 76, temper tantrums, probably tended to exclude a notation of temper display).<sup>1</sup>

A blank space in the tables indicates that a coefficient was not computed, usually because of paucity of cases or because the item would not be applicable to both sexes, e.g., "annoying" girls (Tables 6, 7, 8, 9, or 10).

Probable errors, it will be recalled, were not computed for coefficients smaller than  $0.20$  or  $-0.20$  except for personality-total, conduct-total, and police arrest. In view of the many distorting factors in our data, as described in chapter iv, it appears inadvisable to take much notice of correlations below this size, beyond merely reporting them.

---

<sup>1</sup>Pp. 38-44.

## The Interpretation of Correlation Coefficients

The substance of this monograph must be sought in these tables of correlations. Readers who have learned to think in terms of correlation coefficients will welcome this concise method of statement. Altogether there are about seven thousand coefficients for the boys, and a similar number for the girls, so there is no feasible method of presenting this diffuse material except in tabular form. Since the tables are so constructed as to be self-explanatory, any interpretative or exegetical comment by the writer becomes somewhat superfluous. The reader is invited to make his own interpretation according to his own background or individual interests. Probably few readers will attempt to read the tables consecutively but will prefer to use them for reference as to some specific relationship or to specific groups of correlations.

How must correlation coefficients be read? Everyone is familiar with the fact that a coefficient of 0 means that no correlation or concomitant variation exists between the traits in question; and that intermediate values between 0 and +1.00 represent a positive correlation, i.e., a high degree of the one trait is accompanied more or less by a high degree of the other trait, and a low degree of one trait by a low degree of the other; and that coefficients between 0 and -1.00 represent negative correlation, i.e., high values in one of the traits tend to be associated with low values in the other. Some statisticians have ventured to classify correlation coefficients in the abstract as to whether they are "high," "substantial," "low," or "negligible." Such an evaluation of a correlation without reference to the material on which it is based would seem almost meaningless. A correlation coefficient per se is merely a unit of measurement of relationship analogous to measures of weight, temperature, angular distance, and the like. It would be futile to state whether 10 kilograms is a large or a small weight, without specifying whether we are dealing with coal or with platinum; with gross body weight or with a tumor.

The fundamental understanding of a correlation coefficient from the mathematical standpoint, of course, is in terms of alienation,<sup>2</sup> i.e., the reduction in variability ( $\sigma$ ) of the "dependent"

<sup>2</sup>T. L. Kelley, Statistical Method (New York: Macmillan, 1923), pp. 173-74.

or "predicted" variable associated with differing values of the correlation, according to the factor  $\sqrt{1 - r^2}$ . Upon our material, however, such an interpretation has little meaning, since only a small part of our correlations exceed .50 and an  $r$  of .50 reduces the variability of the dependent variable only to .866 of the variability which would be present in the case of zero correlation—an amount which is scarcely palpable. On the other hand, in comparison with what clinic workers and social scientists must make use of, relationships as high as .50 represent fairly respectable "findings." It is necessary for them to think in terms of low correlations and low probabilities.

With reference to our material, then, correlations greater than .50 are considered "high" on the basis of their rarity. Correlations in our study falling between .40 and .49 may similarly be considered "large," those between .30 and .39 "substantial," and those between .20 and .29 "moderate." Correlations smaller than .20 must be considered of little significance because of the many distorting factors at work in our data. Among negative correlations, those larger than -.20 occurred so infrequently that they must be considered important.

An individual correlation coefficient represents by a simple quantitative symbol the relation between two traits or conditions. It is the mathematical equivalent of the type of statement which one hears commonly among clinical observers, e.g., "Whenever we see a patient with condition A, we may expect the existence also of condition B," or "trait A is usually associated with trait B," or, to illustrate a negative relationship, "the presence of trait A in a patient usually precludes the likelihood of trait B" or "trait A seldom occurs in combination with trait B." The many correlation coefficients in this monograph are intended to serve the same purposes as clinical observations of this type. The advantages of a coefficiential expression lie not only in its more precise, quantitative form but also in the fact that in a routine procedure of computing an  $r$  the weight of contrary instances are not so likely to be overlooked as in the subjective observations arising out of clinical experience. The important limitations of correlation coefficients, in comparison with clinical observations, is that they are not based similarly upon the recognition of process with temporal sequences and consideration of cause-and-effect

relationships but merely state the extent of concomitant variation. They are themselves entirely noncommittal as to temporal or causal implications.<sup>3</sup> Their meaning or utility must be supplied by the reader from his own background and for his own purposes.

At this point it may be desirable to discuss briefly the relation of a "control group" to researches of this kind. The formal description of a control group belongs rather to a research employing the method of "group differences," i.e., a comparison of two groups equivalent in every respect except in the trait which is the basis of comparison. In a study employing correlation coefficients, the control group is comprehended in the computation of the coefficient without a formal mention of the fact. In a bi-serial tabulation for the correlation of depressed spells with chronological age among boys (p. 15) there are 149 cases constituting the "marked" group in which depressed spells were not noted. In a group-differences methodology one would compare such facts as the means, variability, or distribution of ages for each of the two groups. In the tetrachoric tabulation for the correlation of truancy from home with stealing (p. 16) we may consider the 503 boys noted as truant from home as the marked group, the 1,610 boys not noted as truant from home as the control, and compare the incidence of stealing in each group. Or we may divide these cases into the marked group of 815 boys with a notation of stealing and compare the incidence of truancy from home in each group. In our data either method would have been applicable. The method of Pearsonian correlation was chosen because of its conciseness in presenting a large amount of material and because of the fact that correlation coefficients represent a more universalized mode of expression of relationships and fluctuate less with the number of cases (p. 22). If brevity were not so necessary, the method of group differences would be desirable because it would permit a closer analysis of the component parts of a tabulation which a correlation coefficient may obscure.

The question may arise as to whether such a control group is adequate. It may be urged that a proper control group should be obtained entirely outside a clinic population, since the fact of admission to a behavior clinic implies the presence of selective

<sup>3</sup>Pp. 3-7.

factors (pp. 25-27). Now the ideal control group should match the marked group in every respect except the one under study. If the marked group is a series of clinic cases, the control group likewise should be obtained from the same clinic population, in order that whatever selective factors are present in the one group may also be present in the other.

At face value the tables of correlation coefficients may be considered as an effort to describe children's behavior difficulties in terms of correlated behavior problems. The correlations for each of the 111 variates and traits listed in Table 1 have been computed with one another and with the 14 traits or conditions listed in Table 3. A reading of such tables of correlation coefficients as though they were cursive bits of descriptive writing will yield a considerable amount of information, which could be obtained otherwise only through extensive personal clinical observation.

This list is a fairly comprehensive one as far as undesirable behavior is concerned, and in actual experience few behavior difficulties will be encountered which are not included in this list. Unfortunately, the desirable and indifferent behavior traits are seriously underrepresented here because of the prevailing tendency of children's behavior child-guidance clinics to concentrate attention upon the manifestly undesirable traits (pp. 45-46). For that reason the tables afford a description of only one side of the story.

In the tables one will note that among the girls' coefficients there is a larger number of high correlations, both positive and negative, than among the boys' coefficients. The writer does not profess to know the reason. On the one hand, the fact that the girls' coefficients are based upon a smaller number of cases ( $N = 1,181$ ) than the boys' coefficients ( $N = 2,113$ ) will permit a larger number of extreme values. (It is a simple fact in statistics not always appreciated by actual researchers that the smaller the number of cases, the more likelihood that occasional high values will arise purely because of this inadequacy of sampling.) If one considers these correlations in relation to their probable errors, specifically the ratio of coefficient to its P.E., the difference is not so striking. It is possible also that, among our clinic population, selective factors may have served to introduce a greater

amount of heterogeneity into the girls' population than into the boys', so that part of this difference in range of values may be an artifact due to differential selective influences. On the other hand, it is also possible that actually there is a greater amount of heterogeneity among girls on the basis of undesirable behavior than among boys: it may be that girls who become "bad actors" in some respects have a greater tendency to become so in many respects and that therefore the correlation coefficients obtained from such material are enlarged because of the factor of heterogeneity. These are only conjectures. It should be repeated that the writer does not claim to know the reason.

#### Suggestions, Clues, Predictive Values

But the tables of correlation coefficients in this monograph have more than a descriptive utility. Each coefficient represents a relationship between two traits, and many of them indicate important concepts. The mere statement of a correlation is, of course, not the final goal of a research procedure but may be considered as a valuable landmark or guidepost. Our ultimate desire is to be able to trace the process by which certain inherent tendencies of the individual together with environmental factors acting upon him produce a given type of behavior. Here we cannot expect to isolate some one unitary or essential cause, as physicians do in the case of certain infective bodily diseases, but must be prepared to find that the causal factors are multiplex and of differing degrees of potency. It is in the locating of causal factors and measurement of their potency that correlation coefficients serve their unique purpose. In the total procedure, then, the computation of correlations is but a preliminary or exploratory, though useful, step. They indicate the directions which further research should take and suggest relationships which warrant special inquiry in more completely elaborated ad hoc researches.

In addition to the suggestions for further research to be found in such a collection of correlation coefficients, there are two uses of value in actual clinic practice, that of clues to behavior trends not readily observable and that of prediction of future behavior or condition.

As an illustration of the use as clues, let us consider

the substantial tetrachoric correlation of  $.64 \pm .02$  (with age "partialled out") between stealing and truancy from home among our 2,113 boys (p. 16 and Table 56, p. 312). Now stealing is likely to take place more or less in secret, so that its presence in an individual child may often not be known except as a result of special inquiry. Truancy from home, on the other hand, is an overt occurrence well enough known to the child's parents. In view of the high correlation of  $.64 \pm .02$  in our clinic population, the presence of truancy from home raises the question of the presence of stealing. A more meaningful interpretation would be obtained directly from the full tetrachoric tabulations, which unfortunately could not be reproduced here in any great number because of lack of space. In this instance, out of 503 home truants, 375, or 75 per cent, had a notation of stealing, while of 1,610 non-truants only 440, or 27 per cent, had a notation of stealing. Thus the "expectancy" for stealing is almost three times as great among home truants as among non-truants within our clinic population. What this expectancy may be among children in general not subjected to the selective factors, whatever these may be, attendant upon examination in a children's behavior clinic, cannot be easily inferred; but this relation is large enough to imply that the presence of the one trait indicates the advisability of an inquiry into the presence of the other.

A more adequate conjecture or estimate would be obtained by considering the joint evidence of several traits or notations.<sup>4</sup> We note from Table 56 that stealing among boys correlates substantially also with truancy from school ( $.62 \pm .02$ ), lying ( $.61 \pm .02$ ), and bad companions ( $.57 \pm .02$ ). Obviously, the ascertained presence of several of these traits or notations increases the probability of the presence of stealing. For example, we have noted that, of the boys with a case-record notation of truancy from home, 75 per cent had a notation of stealing. Out of the 324 boys with notations both of truancy from home and truancy from school, 265 boys, or 82 per cent, had a notation of stealing. Out of 182 boys with three notations—truancy from home, truancy from school, and lying—87 per cent had a notation of stealing. Out of 76 boys with

---

<sup>4</sup>R. L. Jenkins and Luton Ackerson, "The Study of the Type as a Statistical Method," Journal of Juvenile Research, XVII (1933), 1-9.

the four notations truancy from home, truancy from school, lying, and bad companions, 93 per cent had a notation of stealing.

Another illustration of the use as clues or indicators of the presence of less easily observable traits which may be had from a scrutiny of the tables of correlation coefficients in subsequent pages is in reference to sex delinquency (coitus), which among girls is an item of information often desired in the examination but relatively difficult to ascertain. The correlation coefficients of sex delinquency (coitus) among the girls (Table 96, p. 470) were as follows: with truancy from home,  $.48 \pm .04$ ; with oversuggestibility,  $.38 \pm .04$ ; and with overinterest in opposite sex,  $.38 \pm .04$ . Among 189 girls with a case-record notation of truancy from home 87 girls, or 46 per cent, had a notation of sex delinquency (coitus). Out of 67 girls with notations of both truancy from home and staying out late at night, 51 per cent had notations of sex delinquency (coitus). Out of 19 girls with the three notations truancy from home, staying out late at night, and oversuggestibility, about 58 per cent had also a notation of sex delinquency (coitus). Out of 5 girls with the four notations truancy from home, staying out late at night, oversuggestibility, and overinterest in opposite sex, 4 girls (80 per cent) had also a notation of sex delinquency (coitus).

Within our material, it should be remarked in passing, the probabilities could not be increased indefinitely by this cumulative process. As the number of notations increased, the number of cases decreased (as in the example cited in the last paragraph) to the point where mere fluctuations of sampling blurred the trends. The procedure appeared empirically to be satisfactory, up to the accumulation of three notations, but often unsafe if four or more notations were considered. But in an application of this cumulative process to actual children, among whom paucity of cases cannot enter as a disturbing statistical factor, there is no reason why the cumulative effect of each added notation, which, as in the preceding illustrations, is highly correlated with the notation under discussion, should not increase the probabilities indefinitely. In practice, however, it is likely that the increment in the probabilities to be gained by the addition of fresh notations beyond the first five or six will become almost negligible. The technical reason is that the intercorrelations among the notations themselves

are usually as high as with the notation under discussion and by analogy with "team correlation," high "outside correlations" cannot be obtained if the intercorrelations are also high.<sup>5</sup>

Although the material in this monograph does not enable the reader to calculate the actual probabilities, as in the two illustrations cited above, an application of the Spearman sums-and-differences formula<sup>6</sup> will enable one to infer whether the addition of further notations to the composite can be depended upon to increase the probabilities that a given trait or condition is present. If we consider the notations to represent actual continuous measures and if these are reduced to "standard measures,"<sup>7</sup> i.e., measures so calibrated that their standard deviation becomes unity, this formula becomes delightfully simplified. For example, the correlation of a trait (1) with the combination of two other traits (2 and 3) becomes

$$r_{1(2+3)}(\text{in the case of equal } \sigma\text{'s}) = \frac{r_{12} + r_{13}}{\sqrt{2 + 2r_{23}}}$$

The correlation of a trait (1) with the combination of three others (2, 3, and 4) becomes

$$r_{1(2+3+4)}(\text{in the case of equal } \sigma\text{'s}) = \frac{r_{12} + r_{13} + r_{14}}{\sqrt{3 + 2(r_{23} + r_{24} + r_{34})}}$$

The general formula for the correlation of a trait with the combination of any number of traits similarly becomes

$$r_{1(2+3+4+\dots+n)}(\text{in the case of equal } \sigma\text{'s}) = \frac{r_{12} + r_{13} + r_{14} + \dots + r_{1n}}{\sqrt{(n-1) + 2(r_{23} + r_{24} + \dots + r_{2n} + r_{34} + \dots + r_{3n} + \dots + r_{(n-1)n})}}$$

wherein  $\underline{n}$  denotes the ordinal number of the last notation to be added to the composite.

<sup>5</sup>C. L. Hull, "The Joint Yield from Teams of Tests," Journal of Educational Psychology, XIV (1923), 396-404, or Aptitude Testing (Yonkers: World Book Co., 1928), chap. viii.

<sup>7</sup>Kelley, op. cit., pp. 114-17.

There is no method, of course, of transmuting these correlation coefficients into probabilities. Nor should one expect that the results of this sort of formulaic computation would parallel exactly the probabilities obtained from an actual counting of cases, as in the two illustrations described above. But an empirical comparison of the results of the sums-and-differences formula showed that, whenever the team correlation increased definitely with the addition of a fresh notation, the probabilities also increased. For example, in the two illustrations cited above, the correlations of stealing among boys with truancy from home and with truancy from school were .64 and .62 respectively, and with the composite of the two the team correlation was .70. When a third notation, lying, was added, the correlation with the three became .76; and, when bad companions was added, the team correlation of stealing with the composite of four notations was .79. In the other illustration the correlations of sex delinquency (coitus) among girls with truancy from home and staying out late at night were .48 and .44 respectively, and with the composite of the two the correlation was .53. When a third notation—oversuggestibility—was added, the team correlation was .59; and, when overinterest in opposite sex was added, the correlation of sex delinquency (coitus) with the composite of four notations was .60.

Whenever the addition of a fresh notation brought about a decrease in the sums-and-differences correlation, inferences could not be made as to the effect upon the probabilities. Of the two instances cited below (pp. 76-77), in which the team correlation showed decreases with the addition of certain notations, in one instance (police arrest among boys) the probabilities continued to increase, while in the other (police arrest among girls) the probabilities showed a decrease.

The question arose as to the probable results of re-sorting the cards into fourfold tables for cumulative teams of notations and computing Pearson tetrachoric correlations therefrom. An empirical test quickly showed that this method was not feasible. Among the four instances cited (pp. 70-72 and 76-77), it was found that the tetrachoric coefficient usually increased for the composite of two notations but, beyond this, usually decreased with successive additions of further notations. At least three factors may co-operate in bringing about this irregularity. (1) It may be that

the requirement of normality in tetrachoric correlation is not fulfilled. As far as one notation is concerned, the assumption of normality of distribution is not implausible (pp. 18-19); but, when several notations are compounded, the form of the distribution may become complex and irregular. (2) Or it may be that in such a combination the point of dichotomization becomes equivocal, so that the resultant grouping of cases may tend to neutralize the effect of the underlying correlation. An analysis of the structure of a tetrachoric tabulation will make this clear. On the one side of the dichotomization one would have, for example, the boys with all three notations—truancy from home, truancy from school, and lying—while on the other side of the dichotomization one would have the boys with any two, one, or none of these notations. Now it is possible that many of the boys with two or even one of these notations differ so slightly from those with all three notations that when they are placed in the opposite dichotomy they will tend to counteract the statistical influence of the other boys with all three notations and thus reduce the correlation coefficient. In addition to this effect, there is often a marked decrease in the number of cases in the marked dichotomy, so that any increase in the value of the correlation coefficient resulting from this regrouping of cases on this side of the dichotomization may be more than counterbalanced by the increased number of cases on the other. Or, to speak in terms of the actual tetrachoric tabulation (p. 16), the compounding of additional notations may often increase the ratio of cases in the upper left quadrant to cases in the lower left quadrant, thereby tending to increase the correlation coefficient as far as the left half of the tabulation alone is concerned. On the other hand, such a regrouping will also tend to increase to a small extent the ratio of cases in the upper right quadrant to cases in the lower right quadrant. Even though this increase in ratio in the right half of the tabulation will usually be much less than the increase in the left half, this smaller ratio may nevertheless acquire a predominant influence in the total tabulation because of the large shift of cases from the left half to the right half which usually results from such a regrouping. (3) A third probable factor may be the unsatisfactory amount of validity or consistency (pp. 27-33) in the case notations, e.g., it is probable that in many instances where only two of a given set of

notations are present the third should also have been present if the true facts were known. The effect of this weakness in the data is, of course, ordinarily a reduction in the correlation toward zero. While this possibility of inadequate validity and consistency exists also when we are dealing with one notation, this "attenuation" effect probably becomes multiplied when several notations are involved.

The use of the information comprised in the tables of correlation coefficients as predictions of future behavior is of the same nature as their use as clues, but with the time element added. Let us cite two illustrations, police arrest among boys and among girls (Table 8, p. 107). Among boys the correlations with police arrest were as follows: with truancy from home,  $.68 \pm .02$ ; with stealing,  $.63 \pm .02$ ; with bad companions,  $.59 \pm .02$ ; with truancy from school,  $.57 \pm .02$ ; and with staying out late at night,  $.52 \pm .03$ . Out of 503 boys with a notation of truancy from home, 270 boys, or 54 per cent, had a notation of police arrest. Now in the case of an individual boy who truants from home but has not yet been under police detention, the probability is greater that at some future time he will have a police arrest than the boy with no such notation in his history. (It should be noted that the histories of our children are not yet "completed" in point of time, so that the probabilities as here given are undoubtedly understated as far as our clinic populations are concerned.) In interpreting these probabilities two cautions are necessary. (1) Our population is unquestionably a selected one on the basis of admission to a behavior clinic, and it is impossible to conjecture how closely these percentages correspond to what would be found among unselected children. Our percentages cannot be applied strictly to any other population except that of a behavior clinic with an intake similar to that of this one. (2) Since a time consideration is involved, the question arises as to which behavior trait antedates the other. In the present instance one can readily believe that truancy from home usually occurs prior to police arrest, partly because in many cases the truancy was one of the specific reasons for the police arrest. The data of this monograph do not aid the reader in concluding which comes first. That must be decided from other criteria. Frequently either one of two behavior traits may be antecedent and predisposing to the other interchangeably, e.g., stealing may be

prophetic of truancy from home, and, vice versa, truancy from home may be prophetic of stealing.<sup>8</sup>

The joint evidence of several notations will, within certain limits, increase the possibility of prediction. Out of 372 boys with notations of both truancy from home and stealing, 227 boys, or 61 per cent, had notations of police arrest. When bad companions was added to the composite, the probability arose to 72 per cent of 157 boys. When truancy from school was added, the probability arose to 73 per cent of 120 boys. When staying out late at night was added, the occurrence of notations of police arrest among 54 boys with all five notations arose to 78 per cent.

The use of Spearman sums-and-differences correlations (p. 72) upon this series showed irregular results. For the combination of truancy from home and stealing the sums-and-differences correlation with police arrest among boys arose to .72, and when bad companions was added this correlation increased to .75. But with the addition of truancy from school this correlation decreased to .64, and with the addition of staying out late at night this correlation arose again only to .75.

Let us examine another instance, that of police arrest among girls. Among the highest correlations (Table 8, p. 107) were: with sex delinquency (coitus),  $.76 \pm .02$ ; with truancy from home,  $.67 \pm .03$ ; with oversuggestibility,  $.57 \pm .03$ ; and with staying out late at night,  $.49 \pm .04$ . Out of 218 girls with a notation of sex delinquency (coitus), 126 girls, or 58 per cent, had a notation of police arrest. Out of 87 girls with the two notations—sex delinquency (coitus) and truancy from home—62 girls, or 71 per cent, had a notation of police arrest. When oversuggestibility was added, the probability arose to about 77 per cent of 22 girls. When staying out late at night was added to the composite, the number of cases with all four notations dropped to 11, of whom 7, or about 64 per cent, had a notation of police arrest.

The Spearman sums-and-differences correlations (p. 72) were also irregular. The team correlation of police arrest with

---

<sup>8</sup>An attempt to indicate which traits are likely to appear at different age levels among children on the basis of incidences is given in Vol. I, Figs. 48 and 52. An excellent study of sequences in offenses among juvenile delinquents is reported by Ruth E. Burkey, "A Statistical Study of the Sequence of Successive Delinquencies," Journal of Juvenile Research, XVI (1932), 133-44.

the composite of two notations was .83; with three notations, .89; and for the composite of four notations the sums-and-differences correlation dropped to .86.

In selecting notations to be added to a composite from which one desires either clues to other traits not so easily ascertainable or prediction as to future behavior or condition, these rules should be followed: (1) The notations should be correlated as high as possible with the unascertained trait or condition. (2) The notations should be intercorrelated as low as possible, or even negatively, with the other traits in the composite. (3) Whenever feasible, preference should be given to notations of relatively frequent occurrence in order to avoid too great a reduction in the number of cases.

PART II

THE RELATIVE IMPORTANCE AMONG TRAITS

## CHAPTER VIII

### ON CRITERIA OF "SERIOUSNESS" AMONG BEHAVIOR DIFFICULTIES

In our effort toward a systematic study of children's behavior difficulties our first step has been a canvass of the data for the purpose of obtaining a comprehensive inventory of the problems actually reported by parents and by examining staff. This inventory resulted in an extensive list of about 300 behavior items found to occur oftener than 0.5 per cent among our total 5,000 cases.<sup>1</sup> Out of this list, 135 items which are ordinarily designated as "personality" or "conduct" difficulties and 26 miscellaneous traits or conditions, which occurred often enough to warrant separate statistical treatment, were selected for the investigation reported in Part II of this monograph.

The next step is an evaluation of what, for the lack of better terms, may be called the relative "seriousness" or "ominousness" among these traits. In clinical work with children and also in planning research projects the question arises as to which of the many behavior problems warrant special attention and which are of negligible importance. Is a notation of truancy from home more serious than a notation of stealing? Is seclusiveness more serious than disobedience? How much importance should be attached to enuresis, a frequently noted item in children's behavior clinics?

Ideal criteria of importance or seriousness lie beyond the potentialities of our data. A socially minded worker would wish to estimate seriousness in terms of the social injury resulting from a given pattern of behavior. A more individualistically minded worker would think in terms of the injury or frustration to the child himself. Others would estimate it according to its prognostic implications, i.e., which of two behavior traits augurs

---

<sup>1</sup>This inventory is published in Tables 1-13 of Vol. I. See also the author's "On the Feasibility of Inventorying Children's Behavior Traits," Journal of Juvenile Research, XVI (1932), 32-39.

the less favorable outcome in the future as the child grows to maturity? Several researchers have attempted to evaluate relative seriousness by asking authorities in children's work to rate various traits as to their importance, leaving to each rater his own subjective conception of what he considers importance or seriousness to mean, i.e., the criterion of "consensus of opinion." Our problem was to find some feasible criteria capable of research treatment by quantitative methods.

As objective and measurable criteria of importance or seriousness, we have employed three devices—the personality-total, the conduct-total, and the notation of a police arrest. The personality-total consists of the unweighted enumeration of all the undesirable personality traits noted for each child. For example, if he is noted as seclusive only, his personality-total is 1; if he also daydreams, his total is 2; if he also has inferiority feelings, his total is 3; and so on. The conduct-total is similarly constructed. If he steals only, his conduct-total is 1; if he is also truant from home, his total is 2; if he is also noted as quarrelsome, his conduct-total is 3; and so on. A refinement may have been given these totals by weighting the various component traits according to their importance, for undoubtedly all the components are not of equal importance, e.g., in the conduct sphere, stealing is of greater concern than finicky food habits. There was no feasible technique of ascertaining such differential weightings in our data, however, without resorting to subjectivity, which our methods have tried to avoid as far as possible. It is unlikely, moreover, that such a weighting of the component traits would have changed our correlational findings to any considerable extent. The third criterion is the fact of a police arrest or detention by reason of misconduct. Among our cases this notation was present among about one-fifth of the boys and about one-seventh of the girls.

The assumption underlying these criteria is that any traits which are highly correlated with the extent of personality or conduct deviation as measured by the number of reported behavior difficulties or which are highly associated with the fact of a police arrest or juvenile-court appearance are more "serious" or "ominous," whether as causes or merely as symptoms, than traits only negligibly correlated with these criteria.

Our grouping of behavior problems into personality and

conduct categories does not profess to rest upon any etiological basis but merely follows the customary usage of these terms by child workers. In so far as a distinction can be made, a personality problem is commonly thought to be a comparatively intrinsic trait in an individual, which in an overdeveloped or exaggerated form is associated with a diagnosis of psychosis or psychopathy or similar mental disorder. It is not ordinarily considered to be deserving of punishment or amenable to it. A conduct problem, on the other hand, in an extreme form is usually associated with commitment to a correctional institution in the case of adults and with a spanking or other overt disciplinary expedient among younger children.<sup>2</sup> The reader who wishes to learn more exactly our arbitrary grouping of traits in order to understand the composition of the personality-total and the conduct-total may refer to Volume I, in which the personality problems are listed in Tables 1 and 2 and the conduct problems in Tables 3 and 4.

The question may well be asked concerning the validity of these three criteria, i.e., What is the evidence that they may be accepted as working measures of "seriousness" or "ominousness."

Among the clinic's staff members who were acquainted with the children of our series in a professional capacity it was observed that a child who was commonly considered a "personality case" usually showed a relatively high personality-total, while one considered primarily a "conduct case" usually showed a large conduct-total. Similarly, a child spoken of as "not a behavior problem" usually showed a small inventory of personality and conduct problems. The formal counting-up of his behavior problems thus gave a result which agreed generally with the opinion of the examiners.<sup>3</sup>

The correlations of these totals with the fact of a police arrest indicate the same contrasts. For conduct-total these coefficients were  $.53 \pm .02$  and  $.31 \pm .03$  for boys and girls respectively, while for personality-total these coefficients were only

---

<sup>2</sup>For a further discussion on this point see I, 41-42.

<sup>3</sup>In this connection it may be appropriate to note that the boy with the largest conduct-total among our entire 5,000 cases, the 63 items of which were listed under Case I.P. in Vol. I (pp. 8-10), is at the time of writing (1939) serving his second state penitentiary sentence for serious property offenses, the two incarcerations having been in widely separated states.

.18  $\pm$  .02 and .11  $\pm$  .03 respectively. The correlations of the two totals with the separate behavior notations in Tables 6 and 7 (pp. 89 and 98) showed similar differences. The high correlations for personality-total were usually with traits commonly described as personality problems, e.g., incipient psychosis (unspecified), diagnosis or question of dementia praecox, queer behavior, depressed spells, talking to self without apparent reason, and the like; while the high coefficients for the conduct-total were with such conspicuous conduct difficulties as swearing, disturbing influence in the home, destructiveness, "annoying" girls, truancy from home, disobedience, and stealing. The fact that personality-total is correlated most highly with incipient psychosis (.76  $\pm$  .03 among boys) and diagnosis or question of dementia praecox (.60  $\pm$  .03 among boys) gives strong support to the validity of our personality total, since the recognized psychoses represent the maximum degree of personality disorder.<sup>4</sup>

The validity of the notation of police arrest is scarcely open to question. Our information concerning this item is complete up to the time of the child's examination at the clinic. It includes only those children who have been under police arrest or detention (whether "booked" on formal complaints or not) for reasons of misconduct. It does not include the children brought to the juvenile court by their parents only for advice, unless the child was actually placed under arrest or detention. Its high correlations were with such obvious misconduct as stealing an automobile, truancy from home, stealing (unspecified), robbing a building, home, etc., bad companions, and the like. An attenuating factor is in all likelihood present in the correlations with police arrest, since our children's histories are uncompleted in point of time and a substantial fraction of these children may be expected to encounter a police arrest in subsequent years. While the "partialing out" of chronological age in these coefficients (the correlations of police arrest with age being .29  $\pm$  .02 and .56  $\pm$  .02 for boys and girls respectively) may tend to standardize their

<sup>4</sup>The technical point should be noted here that in the correlations of a given total with a specific behavior notation which it comprises, the specific notation was excluded from that total; e.g., the correlation (bi-serial  $r$ ) of personality-total with queer behavior means the correlation of queer behavior with the aggregate number of personality problems other than queer behavior.

meaning on the basis of "with age constant," it is very probable that they are definitely reduced in size in comparison with what would have been obtained if one could have employed life-histories fully complete in point of time.

The use of three parallel criteria may seem confusing, but there appeared to be no satisfactory basis for combining them into a single criterion measure. A glance at their intercorrelations (Table 4) shows that they are not highly enough intercorrelated to

to be considered as duplicating one another. The data of Table 5 show similarly that the three criteria tend to show differing correlations with the specific behavior traits covered in this study.

The study by E. K. Wickman<sup>5</sup> obtained direct ratings of the

relative seriousness of behavior problems among school children in the form of rankings by a group of 511 teachers and a group of 30 mental hygienists (8 psychiatrists, 4 psychologists, 13 psychiatric social workers, and 5 visiting teachers), all "actually and solely engaged in the study and treatment of behavior disorders of children" in child-guidance clinics (p. 121). He found that there was no agreement between the rankings of these traits by the two groups, the rank-order correlation coefficient being  $-.11$  (p. 122). He concludes that "teachers stress the importance of problems relating to sex, dishonesty, disobedience, disorderliness, and failure to learn. . . . Mental hygienists, on the other hand, consider . . . . unsocial forms of behavior . . . . [withdrawing, recessive characteristics] most serious and discount the stress which teachers lay on anti-social conduct." A perusal of Wickman's Charts XVI and XVIII, which list the relative rankings of the seriousness of traits by teachers and by mental hygienists respectively and a comparison with our own Tables 6 (p. 89) and 7 (p. 98) bring to light the fact that our conduct-total and police-arrest criteria resemble the teachers' rankings, while our personality-

total criterion corresponds rather with the mental hygienists' rankings.

A similar distinction between conduct problems and personality problems in respect to the differing attitudes of parents or college students, on the one hand, and mental hygienists, on the other, was found by R. M. Stogdill<sup>6</sup> in his studies.

At some future time, as our knowledge of behavior difficulties increases, it may be possible to construct a single comprehensive over-all criterion measure; but for the present, in the writer's estimation, the most defensible policy is to treat each criterion as lying in a different plane.

CHAPTER IX

THE PERSONALITY-TOTAL CRITERION

The personality-total is the unweighted sum of all the personality problems reported for an individual child, as we have explained in the preceding chapter. Among our 2,113 White boys the number of personality problems noted per child ranged from 0 to 46, with a mean of 6.5 and a standard deviation of 5.2 (Table 4, p. 85) Among our 1,181 White girls the range was 0-49, the mean, 6.0, and the standard deviation, 5.4. The distribution of the personality-total is shown in Figure 3.

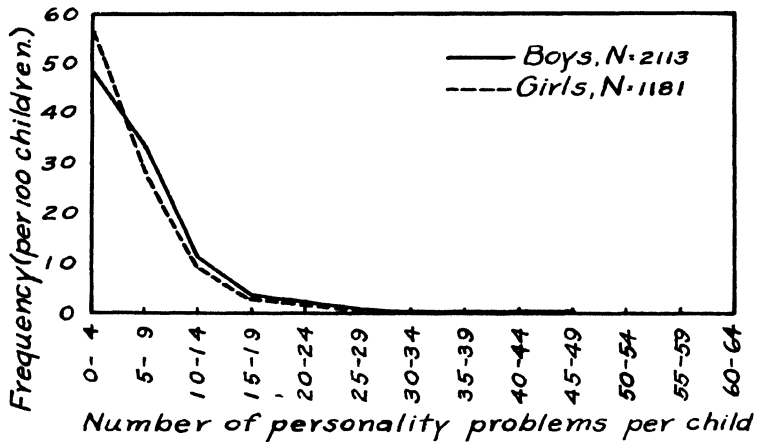

Fig. 3.—Percentage Frequency Distribution of Personality-Totals

In Table 6 it will be noted that the personality-total is strongly correlated with the conduct-total in our data, both among boys and among girls, the product-moment coefficients being  $.50 \pm .01$  and  $.61 \pm .01$  respectively. It is probable that in our data these two coefficients are artificially enlarged because of a.

## Other Correlations (Positive to Negative)

Apprehensive, .19 and .16; Listless, .19 and .16; Discord between parents, .19 and .08; Robbing a building, home, etc., .18 (boys); Truancy from institution, .18 (boys); Former convulsions, .18 and .11; Speech defect, .18 and .11; Refusal to attend school, .17 and .08; Truancy from home, .17 and .19; Mutual masturbation (same sex), .17 (boys); Homosexual (same age), .16 (boys); "Sugar hunger," .16 (boys); Attractive manner, .16 and .05; Clean, .15 and .14; Grouped: dull, slow, etc., .15 and .07; Lack of initiative, .14 and -.03; Bashful, .13 and .05; Vicious home conditions, .13 and .06; Preference for younger children, .12 and .13; Follower, .12 and .07; Victim of sex abuse, .11 (girls); Lack of affection, .10 (boys); Stuttering, .10 (boys); Gang, .09 (boys); Underweight, .09 and .11; Sex delinquency (coitus), .08 and .08; Irregular attendance at school, .07 and -.02; Leader, .05 and .16; Sex denied entirely, .04 and .17; Question of hypophrenia, .04 and -.05; Popular, .03 and .12; Vocational guidance, .02 and .02; Oversuggestible, .01 and .13; Immoral home conditions, .00 and -.03; Slow, dull, -.04 and -.07; Immoral sister, -.07 and -.06; Lues, -.07 and .06; Brother in penal detention, .08 and .12; Retardation in school, -.12 and .13

prejudicial effect due to varying completeness in the case-record data.<sup>1</sup> It can be supposed that the informants who tend to give extensive information concerning the child in the personality sphere of his activity also tend to give extensive data in the conduct sphere, and, similarly, informants who give only a brief account of a child's personality problems are likely to give only limited information as to his conduct difficulties. The personality-total showed relatively low correlations with police arrest, the bi-serial correlations being  $.18 \pm .02$  and  $.11 \pm .03$  for boys and girls respectively.

(In computing the correlations of a specific behavior trait with either the personality-total or the conduct-total of which it would form a component, it was necessary in each instance to exclude the specific behavior notation concerned in the correlation in order to avoid a spurious correlation due to identity of material if both variates were used in the correlation. For example, such a correlation coefficient as that of queer behavior with personality-total among boys,  $.52 \pm .03$ , means the bi-serial correlation of queer behavior with the total number of personality problems noted for each child other than the notation queer behavior itself.)

The highest correlations (bi-serial  $r$ ) among boys with the personality-total criterion of relative seriousness or "ominousness" were with the notations staff diagnosis or question of incipient psychosis or psychosis not elsewhere specified,  $.76 \pm .03$ , and staff diagnosis or question of dementia praecox or schizophrenia (simple, hebephrenic, catatonic, paranoid, or unspecified),  $.60 \pm .03$ ; the corresponding coefficients for girls could not be reliably calculated because of the paucity of girls' cases in our data. Among girls the highest coefficients were for violence,  $.64 \pm .03$ , and queer behavior,  $.61 \pm .03$ , the corresponding coefficients for boys being  $.31 \pm .02$  and  $.52 \pm .03$  respectively. The "larger grouping," depressed spells or unhappiness (undifferentiated), yielded relatively high correlations in the .50's among both sexes.

Eight notations among girls yielded high correlations in

---

<sup>1</sup>Chap. iv, pp. 35-38.

the .50's among girls, and almost equally large coefficients in the .40's among boys: diagnosis or question of encephalitis, question of change of personality, disturbing influence in home, depressed mood or spells, sensitiveness or worrisomeness (undifferentiated), inferiority feelings, boastful or "show-off" manner, and inefficiency in work, play, etc. Four behavior notations among girls yielded high correlations in the .50's and relatively substantial coefficients in the .30's among boys: unpopularity, bossy manner, swearing in general, and failure to adjust in foster-home. Among girls four additional behavior problems yielded high correlations in the .50's and among boys moderate correlations in the .20's: temper tantrums, defiant attitude, resentful attitude, and disturbing influence in school.

Fairly large correlations in the .40's were found among both sexes for fantastical lying, bad language, hatred or jealousy of sibling, and the "larger grouping," "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated), and also for the notation talking to self without apparent reason, for which only the boys' coefficient was computed. Contrariness yielded almost equally large correlations of  $.45 \pm .03$  and  $.38 \pm .04$  among boys and girls respectively. Twelve behavior problems among girls yielded fairly large correlations in the .40's and among boys substantial correlations in the .30's: staff notation or question of psychopathic personality or psychopathic trends, staff notation of psychoneurosis or psychoneurotic trends (unspecified), mental conflict, daydreaming, staff notation of emotional instability, changeable moods, "night terrors," teasing other children, disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), destructiveness, fighting or quarrelsomeness (including violence, undifferentiated), and gluttony or overeating. Eight behavior problems among girls similarly yielded large correlations in the .40's and moderate coefficients ranging from .18 to .28 among boys: abused feeling or manner, quarrelsomeness, fighting, selfishness, leading others into bad conduct, distractibility, irregular sleep habits, and finicky food habits.

Thirteen miscellaneous notations yielded substantial correlations in the .30's with personality-total among both sexes: "nervousness," unhappiness, worry over some specific fact or

episode, sensitiveness in general, sensitiveness over some specific fact or episode, seclusiveness, complaining of bad treatment by other children, rudeness, thumb-sucking, tiring easily, masturbation, overinterest in sex matters, and neurological defect (unspecified). Three additional conduct problems for which only the boys' correlations could be reliably computed also yielded substantial correlations in the .30's: threatening violence, cruelty to animals, and "annoying" girls. Three miscellaneous notations among boys yielded substantial correlations in the .30's, and low or moderate coefficients ranging from .16 to .25 among girls: absent-mindedness, exclusion from school, and headaches. Thirteen miscellaneous case-record notations among girls yielded substantial correlations in the .30's and moderate correlations in the .20's among boys: restlessness, restlessness in sleep, crying spells, egocentricity or selfishness (including self-indulgent attitude [undifferentiated]), disobedience, incorrigibility, stubbornness, sullenness, lying, object of teasing by other children, lack of interest in school, overinterest in the opposite sex, and irregular employment record.

Seven behavior difficulties among both sexes showed moderate correlations in the .20's with the personality-total criterion of seriousness or "ominousness": irritable temperament, sulkiness, "spoiled child," sneakiness, slovenliness, irresponsibility, and nail-biting. A large series of thirteen behavior traits for which only the boys' correlations were computed (the girls' cases being too few) also showed moderate coefficients in the .20's: cruelty to younger children, fire-setting, bullying, swearing at mother, teacher, etc., stealing an automobile or horse, begging on the street, smoking, gambling, obscene language, sex attack or abuse (actual or attempted) upon child of opposite sex, passive pederasty, exhibitionism or "indecent exposure," and bowel incontinence. Five miscellaneous notations among boys showed moderate correlations in the .20's but low positive coefficients below .20 among girls: temper display (other than "tantrums"), laziness, loitering or wandering, poor work in school, and illegitimate parentage. Ten miscellaneous notations among girls showed moderate correlations ranging from .20 to .30, but low positive coefficients below .20 among boys: repressed manner, excuse-forming attitude, egocentricity, stealing, bad companions, truancy from home, staying

out late at night, inattentiveness in school, staff notation of unfavorable conduct prognosis, and enuresis (continuing beyond third birthday).

The only negative correlation of moderate size was for feeble-minded sibling among boys,  $-.20 \pm .03$ , the corresponding coefficient for girls being a low negative,  $-.12$ .

Among the following notations the correlations with the personality-total were found to be quite negligible (less than  $+.10$ ): running with a gang, sex delinquency (coitus), slow or dull manner, question of hypophrenia (suspected feeble-mindedness), immoral home conditions, immoral sister, and question or diagnosis of lues or former lues.

Among the thirteen sex notations considered in this chapter the highest correlation with the personality-total criterion of seriousness was the substantial one of  $.37 \pm .03$  among boys for "annoying" girls. Moderate to substantial coefficients ranging from  $.26$  to  $.35$  among both sexes were found for overinterest in the opposite sex, overinterest in sex matters, and masturbation. Four sex notations for which only the boys' correlations were computed showed moderate correlations in the  $.20$ 's: sex attack or abuse (actual or attempted) upon child of the opposite sex, passive pederasty, exhibitionism or "indecent exposure," and obscene language. The remaining five sex notations (sex delinquency or coitus, mutual masturbation with child of same sex, homosexual practices with child of similar age, victim of sex attack or abuse by older person, and sex misbehavior denied entirely) showed only low or negligible correlations, ranging from  $.04$  to  $.17$ .

Among the twelve physical, psychophysical, or "constitutional" notations considered in this chapter, the highest correlations were with diagnosis or question of encephalitis, with coefficients of  $.41 \pm .03$  and  $.52 \pm .04$  for boys and girls respectively. Neurological defect (unspecified) yielded corresponding substantial coefficients of  $.32 \pm .02$  and  $.39 \pm .03$ . Moderate or substantial corresponding correlations of  $.31 \pm .03$  and  $.25 \pm .04$  were found for headaches. Enuresis (continuing beyond third birthday) among girls and bowel incontinence (computed for boys only) showed moderate correlations in the  $.20$ 's. Low or negligible coefficients ranging from  $-.07$  to  $.18$  were found for the remaining seven notations in this field: underweight condition (10 per cent or more),

"sugar hunger," former convulsions or convulsions in infancy, lues (present or former), speech defect, stuttering, and question of hypophrenia (if mental defect may be classifiable as a "constitutional" disability).

Among the seven home or familial notations considered in this chapter, only two correlations of moderate size were found, both among boys:  $.20 \pm .04$  with illegitimate parentage and the curious negative one of  $-.20 \pm .03$  with feeble-minded sibling. Discord between parents among boys showed the low but statistically significant correlation of  $.19 \pm .02$ . All other coefficients in this field, including those for vicious home conditions, immoral home conditions, immoral sister, and brother with police arrest or under penal detention were low or negligible, ranging from  $-.12$  to  $.13$ .

The correlation coefficients for boys and girls in Table 6 were generally similar to each other, the girls' correlations usually averaging somewhat larger. In other words, notations which from a personality standpoint appeared to be important among boys also appeared to be important in this respect among girls, and vice versa. The rank-order correlation (Spearman's rank-differences-squared formula) for the boys' and girls' coefficients was found to be  $.78 \pm .02$ .

CHAPTER X

THE CONDUCT-TOTAL CRITERION

The conduct-total is the unweighted sum of all conduct problems reported for an individual child, as we have explained in chapter viii. Among our 2,113 White boys the number of conduct notations ranged from 0 to 63, with a mean of 9.4 and a standard deviation of 7.8 (Table 4, p. 85). Among our 1,181 White girls the range was from 0 to 50, the mean 7.6, and the standard deviation 7.2. The distribution of the conduct-total is shown in Figure 4.

Fig. 4.—Percentage Frequency Distribution of Conduct-Totals

It will be noted in Table 7 that among boys the conduct-total showed large correlations with the other two criteria, personality-total and police arrest, the coefficients being  $.50 \pm .01$  and  $.53 \pm .02$  respectively. Among girls the correlations with personality-total were comparatively large ( $.61 \pm .01$ ), but they were of lesser magnitude ( $.31 \pm .03$ ) with the police-arrest criterion. In other words, the extent of conduct deviation among girls appears

## Other Correlations (Positive to Negative)

Nail-biting, .19 and .17; Temper display, .19 and .08; Absent-minded, .18 and .09; Sex delinquency (coitus), .17 and .16; Seclusive, .17 and .17; Former convulsions, .17 and .00; Enuresis, .16 and .18; Irregular attendance at school, .15 and .01; Popular, .13 and .08; Sensitive (general), .12 and .16; Attractive manner, .12 and .08; Vicious home conditions, .12 and .18; Poor work in school, .11 and .08; Preference for younger children, .10 and .15; Brother in penal detention, .10 and -.01; Tiring easily, .09 and .12; Apprehensive, .09 and .16; Listless, .08 and .15; Repressed, .08 and .09; Slow, dull, .07 and -.07; Follower, .07 and .03; Neurological defect, .07 and .12; Clean, .06 and .04; Immoral sister, .04 and .02; Lack of initiative, .02 and -.06; Sex denied entirely, .02 and -.00; Discord between parents, .02 and .16; Immoral home conditions, .01 and .10; Grouped: dull, slow, etc., -.02 and -.03; Bashful, -.02 and -.07; Speech defect, -.03 and .00; Lues, -.03 and .12; Question of hypophrenia, -.03 and -.03; Underweight, -.04 and -.02; Stuttering, -.05 (boys); Retardation in school, -.08 and -.14; Vocational guidance, -.10 and -.17; Feeble-minded sibling, -.15 and -.16

to be more closely related to personality problems than among boys. On the other hand, conduct problems among girls do not seem to be so closely associated with the fact of a police arrest.

(In computing the correlations of a specific conduct notation with the conduct-total, that specific notation was not counted in the conduct-total. For example, the correlation of stealing with the conduct-total among boys,  $.55 \pm .01$ , means the bi-serial correlation of stealing with the total number of conduct problems other than the notation of stealing itself.)

The largest correlation with the conduct-total criterion of seriousness or "ominousness" was the extremely high one of  $.86 \pm .03$  among girls for swearing in general, the corresponding coefficient among boys ( $.51 \pm .02$ ) also being relatively large. (This coefficient of  $.86 \pm .03$ , it may be remarked in passing, is the largest correlation found among all the 14,000-odd coefficients computed in this study.) Violence among girls yielded the unusually large correlation of  $.79 \pm .02$ , the corresponding coefficient among boys being  $.54 \pm .02$ . Staff diagnosis or question of psychopathic personality (unspecified) and disturbing influence in school yielded very high correlations in the .60's among both sexes. Five notations among girls yielded very high correlations in the .60's and among boys almost equally large coefficients in the .50's: leading others into bad conduct, failure to adjust in foster-home, fighting or quarrelsomeness (including violence, undifferentiated), bad language, and disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated). Unpopularity and defiant attitude among girls similarly yielded high correlations in the .60's and among boys fairly large coefficients in the .40's. Queer behavior and abused feeling or manner among girls also yielded very high correlations in the .60's and among boys substantial correlations in the .30's.

High correlations in the .50's were found among both sexes for three conduct difficulties—stealing, incorrigibility, and destructiveness—and also for six conduct difficulties for which only the boys' coefficients were computed: threatening violence, cruelty to younger children, cruelty to animals, begging on the street, obscene language, and "annoying" girls. Truancy from home yielded the meaningful correlations of  $.56 \pm .02$  and  $.42 \pm .03$  among boys and girls respectively. Eight behavior problems among girls yielded high correlations in the .50's and among boys almost equally large coefficients in the .40's: fighting, teasing other children, rudeness, staying out late at night, lying, excuse-forming

attitude, boastful or "show-off" manner, and exclusion from school  
Four notations among girls yielded large correlations in the .50's and among boys fairly substantial coefficients ranging from .29 to .38: temper tantrums, resentful attitude, question of change of personality, and irregular employment record.

Fairly large correlations in the .40's with the conduct-total criterion of seriousness or "ominousness" were found for six conduct difficulties among both sexes: disobedience, disturbing influence in school, truancy from school, fantastical lying, egocentricity, and staff notation of unfavorable conduct prognosis, and also for six conduct problems for which only boys' coefficients were computed: stealing an automobile or horse, truancy or running away from an institution, swearing at mother, teacher, etc., gambling, smoking, and homosexual practices (unspecified) with child of similar age. Three conduct problems among boys yielded large correlations in the .40's and among girls moderate or substantial coefficients ranging from .27 to .35: contrariness, bad companions, and loitering or wandering. Five conduct difficulties among girls yielded large correlations in the .40's and among boys substantial coefficients in the .30's: quarrelsomeness, restlessness, masturbation, overinterest in the opposite sex, and overinterest in sex matters. Ten personality and conduct problems among girls similarly yielded fairly large correlations in the .40's and among boys low or moderate coefficients ranging from .17 to .29: stubbornness, bossy manner, changeable moods or attitudes, staff notation of emotional instability, depressed mood or spells, daydreaming, mental conflict, distractibility, sneakiness, and "night terrors."

Moderate correlations in the .30's among both boys and girls were found for the following eight behavior problems: sullenness, complaining of bad treatment by other children, hatred or jealousy of sibling, "spoiled child," slovenliness, lack of interest or inattentiveness in school studies, employment, etc. (undifferentiated), irregular sleep habits, and gluttony or overeating, and also for the following ten behavior problems for which only the boys' correlations were computed: robbing a building, home, etc., running with a gang, fire-setting, lack of affection for other people, staff diagnosis or question of incipient psychosis or psychosis not elsewhere specified, talking to self without

apparent reason, sex attack or abuse on younger person of opposite sex, mutual masturbation with child of same sex, passive pederasty, and exhibitionism or "indecent exposure." Among boys irritable temperament and refusal to attend school similarly yielded substantial correlations in the .30's and among girls moderate coefficients in the .20's. Among girls seven miscellaneous case-record notations yielded substantial correlations in the .30's and among boys moderate coefficients in the .20's: selfishness, inefficiency in work, play, etc., irresponsibility, restlessness in sleep, unhappiness, crying spells, and diagnosis or question of encephalitis. Three additional case-record notations among girls yielded substantial correlations in the .30's but among boys low positive coefficients below .20: worry over some specific fact or episode, object of teasing by other children, and headaches.

Moderate correlations in the .20's among both boys and girls were found for five behavior problems: sulkiness, inattentiveness in school, lack of interest in school, oversuggestibility, and inferiority feelings and also for four traits for which only the boys' correlations were computed: bullying, staff diagnosis or question of dementia praecox (unspecified), "sugar hunger," and bowel incontinence and also for the notation victim of sex attack or abuse by older child or person, for which only the girls' correlation was computed. Three miscellaneous notations among boys similarly showed moderate correlations in the .20's but low coefficients, ranging from .10 to .19, among girls: laziness, "leader," and illegitimate parentage. Among girls five behavior problems showed moderate correlations in the .20's but among boys low positive correlations below .20: "nervousness," sensitiveness over some specific fact or episode, staff diagnosis or question of psychoneurosis (unspecified) or psychoneurotic trends, finicky food habits, and thumb-sucking.

With the following notations the correlations were found to be quite negligible (less than  $\pm .10$ ): repressed manner, "follower," slow or dull manner, lack of initiative, bashfulness, question of hypophrenia or suspected feeble-mindedness, underweight condition (10 per cent or more), speech defect, stuttering, clean habits, sex misconduct denied entirely, and immoral sister.

Among the thirteen sex notations considered in this chapter the highest correlations with the conduct-total criterion of seri-

ousness or "ominousness" were found for the two conduct difficulties for which only the boys' coefficients were computed: "annoying" girls,  $.56 \pm .03$ , and obscene language,  $.52 \pm .03$ . Three additional notations for which only the boys' correlations were computed yielded very substantial coefficients ranging from .38 to .44: passive pederasty, homosexual practices (unspecified) with child of similar age, and exhibitionism or "indecent exposure." Three sex behavior problems among girls yielded relatively large correlations in the .40's and substantial coefficients in the .30's among boys: overinterest in the opposite sex, overinterest in sex matters, and masturbation. Two sex difficulties for which only the boys' correlations were computed—sex attack or abuse (actual or attempted) upon younger child of opposite sex and mutual masturbation with child of the same sex—yielded respective coefficients of  $.31 \pm .04$  and  $.31 \pm .03$ . Victim of sex attack or abuse by older child or person among girls showed the moderate correlation of  $.21 \pm .03$ , the corresponding coefficient for boys not being calculated because of paucity of boys' cases. Sex delinquency (coitus) showed the low but statistically significant correlations of  $.17 \pm .04$  and  $.16 \pm .03$  among boys and girls respectively. For sex misconduct denied entirely the correlations were quite negligible, .02 and -.00.

Among the twelve physical, psychophysical, or "constitutional" factors considered in this chapter, the largest correlation with conduct-total was for diagnosis or question of encephalitis among girls,  $.36 \pm .04$ , the corresponding coefficient among boys being moderate,  $.20 \pm .04$ . Headaches among girls showed the significant correlation of  $.30 \pm .03$ , the corresponding coefficient among boys being low, .14. Two notations for which only the boys' coefficients were computed—bowel incontinence and "sugar hunger"—showed moderate correlations in the .20's. The remaining eight notations in this field—neurological defect (unspecified), lues (present or former), former convulsions or convulsions in infancy, enuresis (continuing beyond third birthday), underweight condition (10 per cent or more), speech defect, stuttering, and question of hypophrenia (if mental deficiency may be truly classified as a constitutional defect)—all showed only low or negligible correlations, ranging from -.05 to .18.

Among the seven home or familial case-record notations

considered in this chapter the only coefficient of moderate size with conduct-total was for illegitimate parentage among boys,  $.21 \pm .04$ , the corresponding correlation among girls being low,  $.10$ . For the remaining six notations in this field—discord between parents, vicious home conditions, immoral home conditions, brother with police arrest or in penal detention, immoral sister, and feeble-minded sibling—all correlations were low or negligible, ranging from  $-.16$  to  $.18$ .

The correlation coefficients for boys and girls in Table 7 were generally similar to each other. The rank-order correlation (Spearman's rank-differences-squared formula) of the two columns of coefficients in this table was found to be  $.89 \pm .01$ . In other words, the notations which appeared to be important from a conduct standpoint among one sex also appeared to be similarly important among the other sex.

Among boys the correlations with the conduct-total bore little resemblance to those with the personality-total. The rank-order correlation among the boys' coefficients for the two criteria was only  $.33 \pm .05$  (Table 5, p. 86). In other words, a notation which among boys appeared serious from a personality standpoint was not necessarily serious from a conduct standpoint. Among girls the rank order of coefficients was more similar for the two criteria, the intercolumnar correlation of these coefficients being  $.76 \pm .03$ , that is, notations which among girls appeared to be important according to the one criterion also appeared to be important according to the other criterion.

## CHAPTER XI

### THE POLICE-ARREST CRITERION

The notation of police arrest in a child's case record covered any arrest by police for reason of misconduct, whether the child was formally "booked" on charges or not. In many instances a commitment to a penal or correctional institution or to a "parental school" resulted, and in other instances the child was dismissed. It did not include cases in which a child was placed in the "detention home" because of inadequate guardianship by parents. Nor did it include a few instances in which an irresponsible child "wandered away" from his home or his guardians and "became lost" and was taken in charge by police officers for safekeeping until his parents arrived, though some of these instances bordered closely on "truancy." The behavior implied in a police arrest thus varied in seriousness from patent juvenile criminality down to instances of "pickup" for some minor prank or truancy.

Among our children, aged 6 to 17 years inclusive, this notation appeared in 457, or 21.6 per cent, of the 2,113 boys and in 179, or 15.2 per cent, of the 1,181 girls.

Police arrest showed only low correlations with personality-total, the bi-serial  $r$  coefficients being  $.18 \pm .02$  and  $.11 \pm .03$  for boys and girls respectively (Table 8). Among boys the correlation with conduct-total was high,  $.53 \pm .02$ , while among girls the correlation was of less, though substantial, size,  $.31 \pm .03$ .

The largest correlation with police arrest was the unusually high one of  $.76 \pm .02$  with sex delinquency (coitus) among girls, the corresponding boys' coefficient being low but positive,  $.18 \pm .05$ . Very high correlations in the .60's were found for truancy from home among both sexes and also for the two conduct problems for which only the boys' correlations were computed, stealing an automobile and robbing a building, home, etc. Stealing among boys yielded the very large coefficient of  $.63 \pm .02$  and among girls the substantial one of  $.37 \pm .04$ . Three conduct problems among boys yielded high correlations in the .50's and among girls

## Other Correlations (Positive to Negative)

Disturbing influence in home, .19 and .04; Slovenly, .19 and -.02; Victim of sex abuse, .19 (girls); Vicious home conditions, .18 and .15; Swearing (general), .17 and .09; Mental conflict, .16 and .07; Sulky, .16 and .07; Lack of interest in school, .15 and .08; Resentful attitude, .15 and .01; Cruelty to younger children, .14 (boys); Teasing other children, .14 and .04; Apprehensive, .14 and .13; Question of change of personality, .14 and .12; Dementia praecox, .14 (boys); Grouped: egocentric, etc., .14 and .07; Grouped: lack of interest in school, etc., .14 and -.01; Bowel incontinence, .13 (boys); Crying spells, .13 and .07; Discord between parents, .13 and -.01; Leader, .13 and .07; Bully-

TABLE 8—Continued

ing, .12 (boys); Quarrelsome, .11 and .08; Irresponsible, .10 and .08; Nail-biting, .10 and .06; Hatred or jealousy of sibling, .10 and -.11; Clean, .10 and -.03; Popular, .10 and .12; Spoiled child, .09 and .04; Stuttering, .09 (boys); Grouped: temper, etc., .09 and -.06; Inefficient in work, play, etc., .08 and .00; Stubborn, .08 and .09; Temper tantrums, .08 and .03; Listless, .08 and -.01; Queer, .08 and .19; Follower, .08 and .05; Cruelty to animals, .07 (boys); Daydreaming, .07 and .14; Sensitive over specific fact, .07 and .03; Sex denied entirely, .07 and -.16; Former convulsions, .07 and -.19; Temper display, .06 and .06; Restless, .06 and .09; Restless in sleep, .06 and .07; Worry over specific fact, .06 and .00; Immoral sister, .06 and .04; Lack of affection, .05 (boys); Attractive manner, .05 and -.08; Feeble-minded sibling, .05 and .09; Inferiority feelings, .04 and -.02; Headaches, .04 and -.07; "Sugar hunger," .03 (boys); Seclusive, .03 and -.03; Unpopular, .03 and .08; Repressed, .03 and -.14; Question of encephalitis, .03 and .07; Bossy, .02 and -.08; Absent-minded, .02 and -.16; Changeable moods, .02 and .03; Object of teasing, .02 and -.10; Grouped: sensitive or worrisome, etc., .02 and -.02; Talking to self without apparent reason, .01 (boys); Unhappy, .01 and -.02; Abused feeling or manner, .00 and .04; Illegitimate parentage, -.00 and .05; "Night terrors," -.00 and .07; "Nervous," .00 and -.00; Grouped: depressed, etc., -.02 and -.00; Retardation in school, -.03 and -.05; Question of hypochondria, -.03 and -.15; Depressed, -.03 and -.01; Thumb-sucking, -.03 and -.01; Preference for younger children, -.05 and -.14; Distractible, -.05 and .07; Neurological defect, -.06 and -.19; Slow, dull, -.08 and -.16; Speech defect, -.09 and -.08; Grouped: dull, slow, etc., -.12 and -.10; Selfish, -.12 and .15; Tiring easily, -.14 and -.12; Lack of initiative, -.15 and -.12

fairly high coefficients in the .40's: associating with bad companions, staying out late at night, and truancy from school. Over-suggestibility among girls yielded the high correlation of  $.57 \pm .03$ , with a corresponding substantial coefficient among boys of  $.36 \pm .03$ .

Three conduct problems for which only the boys' correlations were computed—running with a gang, truancy or running away from an institution, and begging—yielded large coefficients in the .40's. Leading others into bad conduct and loitering or wandering among boys yielded large correlations in the .40's but among girls moderate coefficients in the .20's. Staff notation of unfavorable conduct prognosis among girls yielded the large correlation of  $.47 \pm .06$  but among boys the moderate coefficient of  $.29 \pm .05$ .

Six conduct problems for which only the boys' correlations were computed yielded substantial coefficients in the .30's: gambling or crap-shooting, swearing at mother, teacher, etc., smoking, sex attack or abuse of younger child of opposite sex, passive pederasty, and mutual masturbation with child of same sex. Four

behavior notations among boys yielded substantial correlations in the .30's and among girls moderate coefficients in the .20's: in-corrugibility, exclusion from school, fantastical lying, and staff notation of psychopathic personality (unspecified). Four case-record notations—refusal to attend school, irregular employment record, destructiveness, and brother in penal detention--yielded substantial correlations in the .30's among boys but low coefficients below .20 among girls. Lying and sneakiness among girls yielded substantial correlations in the .30's and among boys moderate coefficients in the .20's. For immoral home conditions the respective correlations for girls and boys were  $.30 \pm .05$  and  $-.00$ .

Police arrest showed moderate correlations in the .20's among both sexes for the following six behavior traits: fighting, bad language, excuse-forming attitude, emotional instability, over-interest in sex matters, and masturbation and also for the following seven, for which only the boys' coefficients were calculated: threatening violence, fire-setting, staff notation of incipient psychosis (unspecified), obscene language, "annoying" girls, exhibitionism or indecent exposure, and homosexual practices with child of same age. Thirteen undesirable case-record notations showed moderate correlations in the .20's among boys but low coefficients below .20 among girls: violence, disturbing influence in school, disobedience, defiant attitude, contrariness, sullenness, egocentricity, boastful or "show-off" manner, complaining of bad treatment by other children, irregular sleep habits, staff notation of psychoneurotic trends (unspecified), overinterest in opposite sex, and irregular attendance at school. Five miscellaneous notations among girls showed moderate correlations in the .20's but low correlations below .20 among boys: irritable temperament, rudeness, failure to adjust in foster-home, gluttony, and lues (present or former).

Among girls there were several significant negative correlations ranging from  $-.20$  to  $-.30$ : laziness, inattentiveness in school, poor work in school, bashfulness, sensitiveness in general, "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated), finicky food habits, enuresis, and underweight condition. The notation "request for vocational guidance" showed correlations in the  $-.30$ 's for both sexes.

Among the thirteen sex notations considered in chapters

ix-xii of this volume there were many correlations of significant size. The most conspicuous was for sex delinquency (coitus) among girls,  $.76 \pm .02$ . (This is one of the largest correlations found among the approximately fourteen thousand correlation coefficients comprising the data of this volume). This unusually high correlation indicates that heterosexual misbehavior is the major cause among girls for referral to a juvenile court and that known sex misconduct among girls is liable to lead to an appearance in the juvenile court. Among boys the corresponding correlation,  $.18 \pm .05$ , was low but positive. Three sex behavior problems among boys—passive pederasty, mutual masturbation with child of the same sex, and sex attack or abuse (actual or attempted) upon younger child of opposite sex—yielded substantial coefficients in the .30's, the corresponding coefficients for girls not being computed because of the paucity of cases. Three sex behavior notations showed moderate correlations ranging from .18 to .28 among both sexes: overinterest in the opposite sex, overinterest in sex matters, and masturbation and also four notations for which only the boys' coefficients were computed: obscene language, exhibitionism or "indecent exposure", homosexual practices (actual or attempted) with child of similar or younger age, and "annoying" girls. Victim of sex attack or abuse by older child or person (which was calculated only for girls, since the boys' cases were too few) showed the low but significant correlation of  $.19 \pm .05$ . For the notation sex misbehavior denied entirely the correlations were low and not significant,  $.07 \pm .04$  and  $-.16 \pm .06$  for boys and girls respectively.

Among the twelve physical or psychophysical notations there was only one positive coefficient of moderate size in the .20's, lues (present or former) among girls, the boys' coefficient being zero. Among our children the lues may be either congenitally acquired ("inherited") or acquired through sexual behavior of the patient herself, so that this correlation includes to a large extent the correlation of police arrest with sex delinquency (coitus). The correlation of lues with sex delinquency (coitus) (Table 96, p. 470) among girls was  $.23 \pm .05$ ; if we "partial out" sex delinquency (coitus), the resulting correlation of lues with police arrest is reduced to the negligible coefficient of  $-.06$ . The only additional correlations of significant size in this field were the

negative ones in the  $-.20$ 's with enuresis and underweight condition among girls, the corresponding coefficients for boys being negligible. The remaining eight notations showed only low coefficients ranging from  $-.19$  to  $.13$ : question or diagnosis of encephalitis, neurological defect (unspecified), headaches, former convulsions, and speech defect, and the following for which only the boys' correlations were computed: stuttering, bowel incontinence, and "sugar hunger." Question of hypophrenia (if it be permissible to include it among psychophysical notations) showed negligible correlations of  $-.03$  and  $-.15$  with police arrest for boys and girls respectively.

Among the seven notations concerning home or familial conditions there were two correlations of substantial size in the  $.30$ 's: brother in penal detention among boys and immoral home conditions among girls. Vicious (not "immoral") home conditions showed the low but suggestive correlations of  $.18 \pm .05$  and  $.15 \pm .06$  among boys and girls respectively. All other notations in this field (illegitimate parentage, immoral sister, feeble-minded sibling, and discord between parents) showed negligible correlations ranging from  $-.01$  to  $.13$  with police arrest among both sexes.

The following thirty-one miscellaneous notations showed negligible correlations less than  $\pm .10$  with the police-arrest criterion of seriousness or "ominousness" among both boys and girls: stubbornness, temper tantrums, temper display, bossy manner, "nervousness," restlessness, restlessness in sleep, "night terrors," "spoiled child," inferiority feelings, sensitiveness over some specific fact, worry over some specific fact, depressed mood or spells, unhappiness, changeable moods or attitudes, seclusiveness, abused feeling or manner, unpopularity, inefficiency in work, play, etc., listlessness, "follower," distractibility, retardation in school, attractive manner, thumb-sucking, speech defect, question or diagnosis of encephalitis, headaches, illegitimate parentage, immoral sister, and feeble-minded sibling and also four additional notations for which only the boys' correlations were computed: cruelty to animals, lack of affection for others, talking to self without apparent reason, and stuttering.

We may summarize the trends shown by these correlations in this chapter as follows:

1. Behavior notations which constitute specific charges for

arrest are highly correlated with police arrest, as one would suppose, e.g., stealing, truancy, and incorrigibility and, among girls, heterosexual misconduct.

2. Traits which are characteristic of aggressive "bad actors" are highly associated with police arrest, e.g., bad companions and running with a gang, staying out late at night, begging, gambling, smoking, irregular employment record, leading others into bad conduct, and psychopathic personality.

3. Heterosexual misconduct among girls appears to be highly associated with police arrest, but among boys the relation is almost negligible, except in the instances where the misconduct includes an attempt to make a forced attack upon the opposite sex. Passive pederasty, on the other hand, among boys is perceptibly associated with police arrest. This form of misconduct is not of itself often the specific cause of the police arrest, but probably the trait is symptomatic of a grave degree of behavior deviation in that the child may have fallen into a form of homosexual prostitution or may have come under the influence of older aggressive boys or men who have induced him to submit to passive homosexual practices.

4. Among the several notations implying unfavorable home or family conditions, the correlations with police arrest are small or negligible, e.g., immoral or vicious home conditions, brother or sister with police arrest or in penal or correctional institution, immoral sister, illegitimate parentage, and discord between parents. Such a finding is contrary to general expectation; and, since our data did not afford an exhaustive investigation into these factors, no discussion will be made of these correlation coefficients beyond merely reporting them.

The correlation coefficients for the girls bore only a moderate resemblance to those for the boys. The rank-order correlation of the two columns of coefficients in Table 8 was found to be only  $.64 \pm .04$ .

The correlation coefficients with the police-arrest criterion resembled fairly closely those for the conduct-total criterion, the rank-order intercolumnar correlations being  $.70 \pm .03$  and  $.51 \pm .05$  for boys and girls respectively. With the correlation coefficients for the personality-total criterion there was no resemblance the intercolumnar correlations being  $-.05 \pm .06$  and  $.13 \pm .06$  for boys and girls respectively.

## CHAPTER XII

### SUMMARY AND CONCLUSIONS TO PART II

1. The three criteria of importance or seriousness among children's behavior traits employed in this study were accepted because of their objectivity and measurability even though they fall short of ideal criteria which could be conceived of if one resorts to subjective and theoretical terms.

2. The personality-total is the unweighted summation of the specific personality problems noted for each of our 2,113 White boys and 1,181 White girls. The conduct-total is similarly derived from the specific conduct notations. The police-arrest criterion is self-explanatory.

3. Because of the relatively moderate and low intercorrelations among these three criteria, it was deemed inadvisable to combine them into one criterion measure.

4. The personality-total criterion showed results somewhat similar to the conduct-total as far as the girls' correlations were concerned, but with only a slight similarity as far as the boys' correlations were concerned. It showed no similarity to the police-arrest criterion among either sex.

5. The conduct-total criterion showed considerable resemblance to the police-arrest criterion, especially with respect to the boys' correlations.

6. The correlations for the boys were substantially similar to those for the girls in all three criteria.

7. The notations diagnosis or question of dementia praecox and incipient or undiagnosed psychosis (computed only for boys) showed the relatively high bi-serial correlations of  $.76 \pm .03$  and  $.60 \pm .03$  with the personality-total criterion, but low correlations with the other two criteria.

8. The notations queer behavior, depressed mood or spells, unhappy appearance or manner, question of change of personality, changeable moods, and mental conflict yielded high correlations with personality-total among both sexes and with conduct-total

among girls. With police arrest their correlations were negligible or zero.

9. Hatred or jealousy of sibling, inferiority feelings, and daydreaming showed substantial correlations with personality-total, low correlations with conduct-total, and almost no correlation with police arrest.

10. Sensitiveness, worrisomeness, and diagnosis or question of psychoneurotic trends showed substantial correlations with personality-total, but low or negligible correlations with the other two criteria.

11. Boastfulness or "show-off" manner and disturbing influence in the home showed substantial correlations with both personality-total and conduct-total, but low or zero correlations with the police-arrest criterion.

12. Violence, fighting, swearing, resentful attitude, and unpopularity showed especially high correlations with both personality-total and conduct-total among girls. Among boys these correlations were also substantial. Against the police-arrest criterion corresponding correlations ranged from moderate down to negligible in size.

13. Diagnosis or question of psychopathic personality (unspecified) showed high correlations with personality-total and conduct-total and substantial correlations with police arrest. Curiously enough, in spite of its name, it appears to be more associated with overt conduct problems than with personality problems.

14. Diagnosis or question of encephalitis (present or former) and inefficiency in work, play, etc., show high correlations with personality-total, moderate correlations with conduct-total, but negligible or zero relationships with police arrest.

15. The following showed high correlations for both conduct-total and police arrest, but moderate or low correlations with personality-total: truancy from home, truancy from school, staying out late at night, and (calculated for boys only) stealing an automobile.

16. The following showed high correlations with conduct-total and moderate correlations with personality-total and police arrest among both boys and girls: disobedience, incorrigibility, lying, leading others into bad conduct, diagnosis or question of psychopathic personality, and bad language. Similar correlations

were shown by the following four notations, which were calculated only for boys: threatening violence, begging (on the street), "annoying" girls, and obscene language.

17. The following behavior notations showed high or at least substantial correlations with conduct-total, moderate to substantial correlations with personality-total, but low or negligible correlations with police arrest for both boys and girls: fighting, swearing, destructiveness, rudeness, and unpopularity. Similar tendencies were shown by cruelty to younger children and cruelty to animals, which were calculated for boys only.

18. Egocentricity (in behavior or attitude) showed relatively large bi-serial correlations of  $.41 \pm .02$  and  $.48 \pm .03$  for boys and girls respectively for conduct-total, but only very moderate or negligible correlations with either personality-total or police arrest for either sex. Lack of affection for others (calculated for boys only) yielded a moderate correlation with conduct-total, but negligible correlations with the other two criteria.

19. Gambling, smoking, and swearing at mother, teacher, etc. (calculated for boys only) showed moderately high correlations with conduct-total, moderate correlations with police arrest, but fairly low correlations with personality-total.

20. With the police-arrest criterion of seriousness, among both boys and girls, the conspicuous correlations were for such conduct difficulties as stealing, robbery, burglary, truancy from home or from school, associating with bad companions or running with a gang, and staying out late at night. Among girls, the outstanding correlations were for sex delinquency (coitus) and over-suggestibility, both of which showed only low or moderate correlations among the boys.

21. The following case notations showed correlations ranging from moderate to fairly substantial but not high for both sexes with all three criteria of "seriousness" or "ominousness": staff notation of unfavorable conduct prognosis, exclusion from school, contrariness, sneakiness, emotional instability, fantastical lying, irregular sleep habits, masturbation, and overinterest in sex matters. The following five notations (calculated only for boys) showed similar trends: complaining of bad treatment by other children, fire-setting (arson), sex attack on opposite sex, passive pederasty, and exhibitionism (including "indecent exposure").

22. The following long list of traits showed correlations for either sex ranging from moderate to fairly substantial with the personality-total and conduct-total but small or negligible with the police-arrest criterion: temper tantrums, hatred or jealousy of sibling, "spoiled child," violence, fighting, quarrelsomeness, irritable manner, defiant manner, stubbornness, disturbing influence in school, bossy manner, restlessness, restlessness in sleep, egocentric behavior or attitude, selfishness, resentful attitude, sullenness, sulkiness, unhappy manner or appearance, crying spells, changeable moods, question of change of personality, mental conflict, queer behavior, daydreaming, "night terrors," irresponsibility, slovenliness, lack of interest in school, inattentiveness in school, and thumb-sucking. Among the less frequently occurring notations, which were calculated only for the boys, the following showed similar trends: bullying, teasing other children, talking to self without apparent reason, bowel incontinence, and "sugar hunger."

23. Traits associated with mental deficiency and those indicating an unaggressive type of personality tended to show a negligible or even slightly negative correlation with all three criteria of "seriousness" or "ominousness." These were: question of hypophrenia (suspected mental deficiency), slow or dull manner, retardation in school, preference for younger children as playmates, mentally defective sibling, listlessness, lack of initiative, "follower," repressed manner, apprehensiveness, and bashfulness. Bashfulness, in fact, among girls showed a negative tetrachoric correlation of  $-.28 + .04$  with the police-arrest criterion, i.e., bashful girls tended to have greater immunity from police arrest or detention than the nonbashful ones. In a later chapter (Table 10, p. 130) it will be noted that intelligence (IQ) as measured by formal psychometrics (usually the Stanford-Binet of 1916) shows only low or negligible correlations with the three over-all criteria, though with certain specific behavior difficulties it will later be shown that the correlations with formal IQ were occasionally of substantial size.

24. In addition, the following personality traits and physical or home-life conditions showed negligible or occasionally even negative correlations with all three criteria: popularity, "leader," attractive manner, clean habits, sex misbehavior denied

entirely, discord between parents, vicious (as distinguished from "immoral") home conditions, immoral sister, irregular attendance at school, former convulsions, enuresis or bed-wetting (present or former), underweight condition, speech defect, and (calculated for boys only) stuttering. The fact that such unfavorable home conditions as discord between parents and vicious home conditions in our data showed only low or negligible correlations with our over-all criteria of the extent of personality and conduct deviation among children is contrary to the belief held by many social workers. In view of the many inadequacies in our original data, as described in chapter v, the present writer considers it unwise to press the importance of these findings in this controversial topic but prefers to consider them as tentative until more detailed ad hoc studies are available.

25. The case notation brother with police arrest or in penal detention showed among boys the substantial tetrachoric correlation of  $.33 \pm .04$  with the police-arrest criterion, but all other correlations with our three over-all criteria for both sexes were negligible.

26. Exclusion or suspension from school showed moderate to high correlations with all three criteria, especially with conduct-total.

27. Immoral (as distinguished from "vicious") home conditions among our girls showed the significant tetrachoric correlation of  $.30 \pm .05$  with police arrest, but only negligible correlations with the other two criteria.

28. "Nervousness," which in our data was a vague and poorly defined term, showed moderate correlations among our girls with all three criteria, but among boys only with the personality-total criterion. The boys' correlations with the other two criteria were low or zero.

29. A brief consideration of the "seriousness" of the half-dozen most frequently appearing overt conduct difficulties in our case-record data elicits the following. Stealing among both sexes showed moderate correlations with both conduct-total and police arrest, but only low or moderate correlations with personality-total. Lying, fighting, and incorrigibility showed high correlations among both sexes with the conduct-total criterion, and moderate or substantial correlations with personality-total and police arrest.

Truancy from home and truancy from school among both sexes showed generally high correlations with both conduct-total and police arrest, but low correlations with personality-total.

30. Sex behavior problems in our material tended in the main to be intercorrelated with one another to a substantial or high degree, but only to a moderate or negligible extent with non-sex case notations. Sex delinquency (defined strictly as coitus with opposite sex) among girls showed the unusually high tetrachoric correlation of  $.76 \pm .02$  with police arrest, but all other correlations for either boys or girls with our three criteria of "seriousness" were all but negligible. Sex attack or sex abuse, actual or attempted, upon child of opposite sex and "annoying" girls, i.e., lifting their dresses or requesting sexual intercourse (both calculated only for boys) showed moderate to substantial correlations with all three criteria. Masturbation (including questionable and former masturbation), which was noted in about 28 per cent of our 2,113 White boys and in about 13 per cent of our 1,181 White girls, showed moderate correlations ranging from .20 to .41 with all three criteria, similar correlations being found for mutual masturbation with child of same sex and age, which was calculated for boys only. The three sex notations passive pederasty with older person, homosexual activities (unspecified) with child of similar age, and exhibitionism (including "indecent exposure"), which were calculated for boys only, yielded moderate to substantial correlations ranging from .16 to .44 with all three criteria. Manifesting a precocious or excessive interest in the opposite sex and manifesting a precocious or excessive interest in sex matters also yielded moderate to substantial correlations ranging from .18 to .47 with all three criteria of "seriousness" or "ominousness."

31. Among sex notations not considered as personality or conduct difficulties the correlations with our three criteria of "seriousness" generally were of low magnitude. Victim of actual or attempted rape or sex abuse by older person (not a relative), calculated for girls only, yielded a bi-serial correlation of  $.21 \pm .03$  with the conduct-total and a tetrachoric correlation of  $.19 \pm .05$  with police arrest and a negligible correlation with personality-total. Staff diagnosis or question of lues among our cases usually denoted a congenital or "innocently acquired" syphilis and its correlations with our three criteria of "seriousness" were very

negligible for both sexes, except for its correlation of  $.24 \pm .05$  among girls with police arrest. In this case it is probable that the infection was often acquired through "sex delinquency," which in our data was highly correlated with the fact of a police arrest or detention among girls. The correlations for immoral (as distinguished from "vicious") home conditions were similarly negligible for both sexes except for the tetrachoric correlation of  $.30 \pm .05$  with police arrest among girls. For the notation immoral sister (or half-sister) all correlations for both boys and girls with our three criteria were practically zero. Among our boys from illegitimate parentage, the bi-serial correlations with personality-total and conduct-total were  $.20 \pm .04$  and  $.21 \pm .04$  respectively, while with police arrest the boys' tetrachoric correlation came out at zero; among our girls, all three correlations were practically zero. The notation sex misbehavior denied entirely among boys yielded approximately zero correlations, while among girls the correlations with personality-total and police-arrest criteria were  $.17 \pm .04$  and  $-.16 \pm .06$  respectively, while its correlation with conduct-total was zero.

32. Four other behavior items, which were mentioned frequently in the social histories may be briefly noted here. Enuresis (bed-wetting continuing beyond the third birthday) among girls yielded the negative tetrachoric correlation of  $-.25 \pm .04$  with the police-arrest criterion. All other correlations for both sexes with the three criteria were positive but low. Thumb-sucking (including finger- and knuckle-sucking) and nail-biting both showed moderate correlations with personality-total but low positive correlations with conduct-total and negligible correlations with police arrest. Finicky or capricious food habits among girls yielded the fairly substantial bi-serial correlation of  $.41 \pm .03$  with personality-total and the moderate correlations of  $.28 \pm .03$  and  $.26 \pm .05$  with the conduct-total and police-arrest criteria respectively. Among boys its bi-serial correlation was  $.26 \pm .02$  with personality-total, but with the conduct-total and police-arrest criteria its correlations were negligible.

The foregoing several chapters of Part II have attempted to survey the relative "seriousness" or "ominousness" of typical children's behavior traits as measured by over eight hundred correlation coefficients computed with our three criteria. It has

been necessary to limit discussion to only the outstanding indications in this diffuse material. The reader who desires a closer understanding of the importance or significance of specific behavior traits is advised to consult the more detailed correlational analyses which are presented and described in Part III, which concerns the intercorrelations of over a hundred behavior notations with one another.

PART III

INTERRELATIONS AMONG TRAITS

## INTRODUCTORY

The essential contribution of Part III consists in a series of one hundred and twenty-five tables of correlation coefficients. These represent the intercorrelations of 111 behavior traits, chiefly personality problems and conduct difficulties, with one another and their correlations with a selection of 14 miscellaneous physical and educational conditions and home-life circumstances. The "meat" of the succeeding chapters lies in these tables, which consist of about 14,000 correlation coefficients. To the reader who has learned to appreciate the conciseness and universality of correlation coefficients as a means of expressing relationships, the writer's interpretative comments will seem superfluous and repetitious.

In chapter v we described the construction of the tables. In chapter vii we attempted to explain how the correlation coefficients in this study may be interpreted in terms of their practical and social significance. As a description of a behavior trait in terms of its correlates, their purpose is obvious. Their use as clinical clues to other behavior traits not so easily ascertainable or as predictions of expected future behavior was described in considerable detail in chapter vii.

It should be recalled that the cases considered in this volume were White children between the ages of 6 and 17, inclusive, and with intelligence quotients ranging from 50 to over 150. The exclusion of the very young and the very mentally defective, together with several small groups of other non-typical cases, as described in chapter ii, was made in an effort to obtain a group of children more representative of "normal" children. Chronological age was "partialed out" for all tables except those for chronological age and intelligence quotient.

## CHAPTER XIII

### CHRONOLOGICAL AGE AND INTELLIGENCE (IQ)

The relations of children's behavior problems to the factors of age and of intelligence as measured by intelligence quotient (usually from the Stanford-Binet of 1916) were described in Part III of Volume I by means of charts showing the incidence of a given trait for each age and intelligence level, as well as occasionally by means of correlation coefficients. It seemed apparent from those charts that the relationships tended to be curvilinear rather than rectilinear. Furthermore, the effect of age and intelligence is so intertwined that their correlations with the development of behavior difficulties cannot be adequately represented by the usual graphical or coefficiential methods. Our statement of this apparent relation was as follows:

Our hypothesis is that the interaction of the age factor and the intelligence factor produces the resultant effect of increasing the number of behavior problems within the lower age and IQ ranges, and of inhibiting them within the upper age and IQ ranges within our group of children below 18 years of age. It is probable also that either the age factor or the intelligence factor alone, if the other factor were held constant, would likewise produce this "waxing and waning" effect. The process, so far as developmental factors are concerned, is probably a matter of learning and "unlearning."<sup>1</sup>

The reader who compares the material of this chapter with that of Volume I should bear in mind another qualifying circumstance. In the correlations discussed in the present chapter children below 6 years of age and those whose IQ fell below 50 were excluded, and as a result the correlation coefficients of this chapter will tend to be lower because of the reduction in range or variability.

This chapter will thus discuss the relation of age and intelligence quotient to other traits in a briefer manner. The factor of non-curvilinearity of regression probably must be taken into

---

<sup>1</sup>See I, 254-55.

consideration in interpreting all the coefficients in this chapter.

The mean age for our 2,113 boys in the present study was 12.0 years, with a standard deviation of 2.9. For the 1,181 girls the corresponding constants were 12.2 and 3.1 respectively.

The correlation coefficients for chronological age or maturation (Table 9) in general were low. The largest was found to be for diagnosis or question of dementia praecox (calculated only for boys) with a substantial bi-serial  $r$  of  $.40 \pm .02$ . Diagnosis or question of incipient psychosis (unspecified), which was calculated only for boys, also showed the moderate correlation of  $.24 \pm .02$ . Diagnosis or question of psychopathic personality showed the low but positive correlations of .15 and .18 for boys and girls respectively. For diagnosis or question of psychoneurotic trends, however, our correlations were about zero. In addition to the psychiatric notations above, heterosexual behavior items, as one might suppose, tend to become more numerous with increasing age or maturation, especially among girls. Sex delinquency (coitus) among girls yielded the relatively high bi-serial  $r$  of  $.52 \pm .02$  and among boys the moderate correlation of  $.24 \pm .02$ . Similar correlations of lesser size were found for overinterest in opposite sex. Among girls several other conduct difficulties frequently associated with heterosexual behavior also show moderate to substantial correlations with age. These were staff notation of unfavorable conduct prognosis, staying out late at night, truancy from home, and associating with bad companions. Masturbation among girls, however, showed a moderate negative correlation of  $-.21 \pm .04$  and also a negligible negative correlation among boys.

Several behavior notations associated with immaturity showed low to moderate negative correlations with chronological age: speech defect (other than stuttering), enuresis (still continuing), bowel incontinence, thumb-sucking, restlessness, distractibility, destructiveness, fire-setting (calculated for boys only), fighting, disturbing influence in school, and apprehensiveness.

Among numerous notations which showed zero relationships with age or maturation were inferiority feelings, mental conflict, hatred or jealousy of sibling, "spoiled child", daydreaming, queer behavior, sensitiveness (general), boastful or "show-off" manner, staff diagnosis or question of psychoneurotic trends, irritable behavior, changeable moods, emotional instability, sulkiness,

contrariness, clean habits, attractive manner, "follower," nail-biting, stealing, truancy from school, lack of interest in school, poor work in school, disobedience, defiant attitude, incorrigibility, stubbornness, bad language, swearing (general), quarrelsomeness, selfishness, egocentric attitude or behavior, loitering, overinterest in sex matters, and the following six sex notations which were calculated for boys only: sex attack or abuse of little girl, exhibitionism (including "indecent exposure"), mutual masturbation with same sex, homosexual behavior with child of same age, passive pederasty, and obscene language.

The correlations for girls with the factor of age or maturation tended to be of larger size in the notations concerning heterosexual behavior, but in other respects the coefficients for both boys and girls tended to resemble each other.

Intelligence quotient (Table 10) was measured usually by the Stanford-Binet of 1916, but in certain cases by a Kuhlmann-Binet or by an Army or Arthur performance test. (In computing IQ

(boys); Lack of initiative, .04 and .07; Neurological defect, .04 and .11; Fighting, .04 and .10; Disobedient, .04 and .10; Bullying, .04 (boys); Queer, .03 and .13; Irregular sleep habits, .03 and .10; Passive pederasty, .03 (boys); Complaining of bad treatment by other children, .03 and -.03; Truancy from home, .02 and -.03; Question of encephalitis, .02 and .05; Seclusive, .02 and .12; Incurable, .02 and .03; Grouped: swearing, etc., .02 and -.06; Headaches, .02 and .01; Gluttony, .02 and -.03; Sulky, .01 and .10; Listless, .01 and -.11; Loitering, .01 and -.13; Obscene language, .01 (boys); Gambling, .00 (boys); Swearing at mother, teacher, etc., .00 (boys); Leading others into bad conduct, -.00 and -.00; Cruelty to younger children, -.00 (boys); Immoral sister, -.01 and -.06; Exhibitionism, -.01 (boys); Sullen, -.01 and .03; Staying out late at night, -.01 and -.05; Smoking, -.01 (boys); Disturbing influence in school, -.01 and .04; Brother in penal detention, -.02 and -.06; Dementia praecox, -.02 (boys); Violence, -.02 and .04; Temper display, -.02 and .05; Bowel incontinence, -.02 and .02; Gang, -.02 (boys); Stuttering, -.03 (boys); Swearing (general), -.03 and .04; Refusal to attend school, -.03 and -.08; Distractible, -.04 and .06; Stealing an automobile, -.04 (boys); Object of teasing, -.05 and -.08; Threatening violence, -.05 (boys); Apprehensive, -.06 and -.01; Underweight, -.06 and -.07; Poor work in school, -.06 and -.13; Follower, -.07 and -.04; Irregular employment record, -.07 and -.04; Truancy from school, -.07 and .02; Former convulsions, -.07 and -.07; Robbing a building, home, etc., -.08 (boys); Irregular attendance at school, -.08 and -.12; Victim of sex abuse, -.09 (girls); Speech defect, -.09 and -.15; Exclusion from school, -.10 and -.03; Talking to self without reason, -.10 (boys); Preference for younger children, -.12 and -.19; Conduct prognosis bad, -.18 and -.12; Oversuggestible, -.19 and -.14

among older children the denominator of 16 years' chronological age was used during the years in which these children were examined.) As explained in earlier pages, the range of IQ within this group was from 50 to over 150. The mean IQ of our 2,113 boys was 83.0 and the standard deviation, 17.1. For the 1,181 girls the corresponding constants were 81.6 and 16.1 respectively. This group thus forms an artificial and truncated distribution with respect to intelligence, and it is probable that the correlations based on it are likely to be reduced in size toward zero because of the effect of these restrictions of range.<sup>2</sup>

With the personality-total and the conduct-total the product-moment correlations were all low but positive, indicating that the more intelligent children in our clinic population tended to manifest a slightly larger number of behavior difficulties than the less intelligent. Since these relationships, however, were shown in Part III of Volume I to be of a curvilinear character,

<sup>2</sup>T. L. Kelley, Statistical Method (New York: Macmillan, 1923), pp. 314-16.

they are not adequately measured by the coefficients of the product-moment family, including bi-serial  $r$  and tetrachoric  $r$ , which presuppose only a rectilinear relationship. The interested reader, therefore, is referred to our previous volume, in which the data were more closely analyzed by separation into more restricted and homogeneous age and intelligence groupings, and wherein the relationships were represented graphically. These qualifications must probably be considered also in interpreting the remainder of the correlations in Table 10.

With police arrest the coefficients were of negligible size and negative sign.

The correlations (bi-serial  $r$ ) of intelligence quotient with the separate behavior and other notations were generally of low magnitude, probably owing in some measure to the technical factors of curvilinearity of regression in these relationships and restriction of range, as described above. Only a few coefficients were larger than  $\pm .20$ .

The highest coefficients were negative: for retardation in school,  $-.70 \pm .01$  and  $-.70 \pm .02$ , among boys and girls respectively, and for question of hypophrenia or suspected mental deficiency (not a staff notation),  $-.57 \pm .02$  and  $-.53 \pm .02$ . Slow, dull manner also yielded negative correlations of moderate size.

Among the positive correlations the largest were of only moderate size: repressed manner, hatred or jealousy of sibling, daydreaming, bossy manner, mental conflict, and boastful or "show-off" manner. In addition, the following showed moderate correlations in the .20's among boys but lesser correlations among girls: attractive manner, sensitiveness or worrisomeness (undifferentiated), inferiority feelings, popularity, psychoneurotic trends, and (calculated among boys only) sex attack or abuse of young girl. The following showed moderate correlations ranging from .20 to .32 among girls, but lower correlations among boys: "leader," egocentricity, selfishness, abused feeling or manner, sneakiness, "spoiled child," and thumb-sucking.

Three other behavior notations which are frequently found in the case histories of mental defectives showed low negative correlations with IQ among our cases: oversuggestibility, preference for younger children as playmates, and object of teasing by other children. If these correlation coefficients seem lower than might

be expected, it must be recalled that this group is a somewhat artificial one with restricted range, as explained previously, and our coefficients involving these three notations would probably be much larger if a selection of all IQ ranges were used.

An interesting comparison may be made between the correlations of Table 10 and the corresponding coefficients in Table 37 (p. 241) for question of hypophrenia (suspected mental deficiency). The latter notation was not made by the professional staff of the clinic, nor was it based directly upon a psychometric score. It was the subjective opinion or conjecture made by a parent, teacher, family friend, or social-agency worker prior to the child's admission to the clinic. Although one series was based upon objective psychometric ratings while the other was a matter of subjective "lay" opinion, it is evident that the corresponding coefficients usually showed similar trends (although the coefficients would be of opposite sign because of the antithetic meaning of the two notations). Retardation in school with its very high bi-serial correlations of  $-.70$  for both boys and girls curiously enough showed a closer agreement with IQ than with question of hypophrenia, with which its tetrachoric correlations were  $.55 \pm .02$  and  $.48 \pm .03$  for boys and girls respectively.<sup>3</sup>

---

<sup>3</sup>A brief summary and comparison of these two series of correlations may be found in the author's "Behavior Traits of High-Grade Mental Defectives (a Statistical Study)," Proceedings of the Fifty-ninth Annual Session of the American Association on Mental Deficiency, Chicago, XL (1935), 435-43. See also the concluding paragraph of chap. xxv.

## CHAPTER XIV

### DEPRESSED MOOD OR SPELLS; UNHAPPY APPEARANCE OR MANNER; CRYING SPELLS

Depressed or discouraged attitude or spells of depression or discouragement in our study was considered as a more profound emotional state than unhappy or discontented appearance or manner. The notation crying spells or crying easily was used to designate merely an overt behavior pattern without regard to the depth of any underlying emotion. A fundamental difference between the three notations is in their genetic aspects as shown in our Volume I (Fig. 48, pp. 204-7). Among 2,779 White boys and 1,675 White girls of ages ranging from infancy to 17.9 years of age and of IQ ranges from about 0 to over 150, crying spells or crying easily appeared characteristic during the earlier years of age, unhappiness or discontent during an older age, and depressed spells during a still later age. All three traits yielded numerous substantial correlations with other behavior problems, especially of "personality" type, and should be considered important notations from a clinical standpoint, though of little significance as far as overt juvenile delinquency is concerned, as one may infer from their lack of correlation with police arrest. Our justification for treating depressed and unhappy as two separate behavior entities lies in the fact that their correlations with other traits showed many divergences and also that the combining of the two groups of cases under one rubric (as shown in Table 13, p. 144) did not appreciably increase the size of the resulting correlation coefficients, which would have occurred if these two notations were really the same entity.<sup>1</sup>

The notation depressed, discouraged attitude; spells of depression or discouragement appeared among 149 of our 2,113 White boys, or in 7.1 per cent, and among 73 of our 1,181 White girls,

<sup>1</sup>See chap. iv, pp. 38-44.

or in 6.2 per cent. It was of marked clinical importance as an indicator of personality deviation, its bi-serial correlations with the personality-total being  $.42 \pm .03$  and  $.55 \pm .03$  among boys and girls respectively. Among girls it was of considerable significance also as an indicator of conduct difficulties, the correlation with the conduct-total being  $.43 \pm .03$ , but among boys its relation with the conduct-total was of little importance, the corresponding bi-serial correlation being only  $.17 \pm .03$ . It appears to have no relation with our police-arrest criterion of overt juvenile delinquency, since its tetrachoric correlations among both sexes were practically zero.

Its highest correlation as shown in Table 11 was with changeable moods among girls,  $.51 \pm .05$ , the corresponding correlation among boys,  $.28 \pm .04$ , being of moderate size. Six personality notations yielded substantial or large correlations ranging

.16 and .01; Grouped: fighting, etc., .16 and .19; Attractive manner, .15 and .05; Disobedient, .14 and -.03; Refusal to attend school, .14 and -.13; Finicky food habits, .13 and .17; Smoking, .13 (boys); Lack of interest in school, .12 and .07; Teasing other children, .12 (boys); Spoiled child, .12 and .14; Immoral home conditions, .12 and .15; Grouped: swearing, etc., .12 and .07; Swearing (general), .11 (boys); Threatening violence, .11 (boys); Bashful, .11 and .14; Victim of sex abuse, .11 (girls); Disturbing influence in school, .10 and .13; Incurable, .10 and .15; Object of teasing, .10 and .14; Clean, .10 and .15; Grouped: lack of interest in school, etc., .10 and .09; Fighting, .09 and .12; Temper display, .09 and .17; Complaining of bad treatment by other children, .09 (boys); Apprehensive, .08 and .09; Headaches, .08 and .09; Irregular attendance at school, .08 and -.03; Vicious home conditions, .08 and -.02; Lying, .07 and .14; Quarrelsome, .07 and .18; Overinterest in sex matters, .07 and .16; Exclusion from school, .07 and .10; Speech defect, .06 and -.05; Lack of initiative, .05 and .01; Preference for younger children, .05 and -.05; Former convulsions, .05 and .05; Excuse-forming, .04 and .13; Underweight, .04 and -.00; Enuresis, .03 and .18; Poor work in school, .03 and .05; Irresponsible, .02 and .18; Loitering, .01 and .01; Conduct prognosis bad, .01 and .12; Stuttering, .01 (boys); Follower, .01 and -.19; Vocational guidance, .01 and -.00; Destructive, -.02 and .17; Inattentive in school, -.02 and .08; Oversuggestible, -.02 and .08; Popular, -.03 and -.13; Bad companions, -.04 and .07; Stealing, -.07 and .18; Truancy from school, -.08 and .02; Leader, -.08 and .09; Lues, -.09 and -.01; Gang, -.09 (boys); Staying out late at night, -.11 and .09; Truancy from home, -.11 and .07; Brother in penal detention, -.12 and -.13  
Omitted—Grouped: depressed, etc.

from .31 to .47 among both sexes: unhappiness, sensitiveness in general, sensitiveness over some specific fact or episode, worry over some specific fact or episode, daydreaming, and staff notation or question of psychoneurotic trend. Queer behavior and stubbornness among girls yielded large correlations in the .40's, but among boys low positive correlations below .20.

Six personality problems yielded substantial correlations in the .30's among girls and moderate correlations in the .20's among boys: crying spells, inferiority feelings, mental conflict, seclusiveness, question of change of personality, and hatred or jealousy of sibling. An additional five personality and conduct difficulties yielded substantial correlations in the .30's among girls but low correlations below .20 among boys: repressed manner, disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), temper tantrums, bossy manner, and distractibility.

With depressed mood or spells four personality notations showed moderate correlations in the .20's among both sexes: emotional instability, unpopularity, listlessness, and "nervousness"

or restlessness (including irritable temperament and changeable moods, undifferentiated). Question of encephalitis and neurological defect (unspecified) showed moderate correlations in the .20's among boys but low positive coefficients below .20 among girls. Sixteen miscellaneous behavior notations among girls showed moderate correlations in the .20's, but low coefficients, ranging from -.02 to .19, among boys: sullenness, sulkiness, slovenliness, laziness, absent-mindedness, fantastical lying, boastful or "show-off" manner, selfishness, egocentricity, contrariness, leading others into bad conduct, violence, irregular sleep habits, restlessness in sleep, masturbation, and sex misbehavior denied entirely.

Two case-record notations showed significant negative correlations in the -.20's, both among girls: retardation in school and question of hypophrenia.

The tetrachoric correlation of depressed mood or spells with the notation feeble-minded sibling could not be calculated for either boys or girls because there were no instances in our data in which a child's case record showed both notations.

Among the six sex notations (which are being considered throughout Part III) there were found only two positive correlations of moderate size in the .20's, both among boys—masturbation and sex misbehavior denied entirely—all other correlations in this field being low or negligible.

Among the seven physical or psychophysical notations the only correlations of moderate size in the .20's were for question of encephalitis and neurological defect (unspecified), both among boys.

Among the four home or familial notations all correlations with depressed mood or spells were low or negligible.

The notation unhappy or discontented attitude, appearance, or manner appeared in 95 boys' cases, or 4.5 per cent, and among 64 of our girls' cases, or 5.4 per cent. Its correlations as shown in Table 12 were somewhat similar to those for depressed mood or spells but slightly lower. The most conspicuous difference is that among our boys unhappiness tended to show more significant correlations with overt conduct problems than were found for depressed mood or spells.

Among both sexes unhappiness showed fairly substantial

## Other Correlations (Positive to Negative)

Lying, .19 and .15; Complaining of bad treatment by other children, .18 (boys); Spoiled child, .18 and -.00; Threatening violence, .18 (boys); Destructive, .18 and .11; Disobedient, .17 and .17; Slovenly, .17 and .09; Worry over specific fact, .16 and -.04; Swearing (general), .16 (boys); Fantastical lying, .15 and -.16; Irregular sleep habits, .15 and .10; Attractive manner, .15 and .02; Grouped: "nervous," etc., .14 and .16; Grouped: temper, etc., .14 and .07; Neurological defect, .14 and .12; Poor work in school, .14 and .09; Stealing, .13 and .06; Stubborn, .13 and .07; Listless, .13 and .13; Former convulsions, .13 and -.07; Grouped: egocentric, etc., .13 and .10; Speech defect, .12 and -.10; Bashful, .12 and .08; Quarrelsome, .11 and .19; Egocentric, .11 and .17; Immoral home conditions, .11 and .07; Grouped: dull, slow, etc., .11 and .01; Grouped: lack of interest in school, etc., .11 and .14; Object of teasing, .10 and .12; "Nervous," .10 and .18; Psychoneurotic, .10 and .04; Smoking, .10 (boys); Disturbing influence in school, .10 and .10; Finicky food habits, .10 and .12; Clean, .09 and .09; Sex denied entirely, .09 and .11; Headaches, .09 and .10; Vocational guidance, .08 and .17; Sex delinquency (coitus), .08 and .01; Preference for younger children, .07 and -.01; Follower, .07 and -.03; Emotional instability, .06 and .16; Conduct prognosis bad, .06 and -.02; Unpopular, .06 and .09; Irritable, .06 and .14; Truancy from school, .05 and .08; Absent-minded, .04 and .07; Teasing other children, .04 (boys); Selfish, .04 and -.15; Enuresis, .04 and -.01; Slow, dull, .03 and .02; Vicious home conditions, .03 and .13; Lues, .02 and .02; Restless in sleep, .02 and -.01; Gang, .01 (boys); Temper tantrums, .01 and .14; Popular, .01 and .05; Fighting, -.01 and .19; Irregular attendance at school, -.01 and -.04; Distractible, -.02 and .12; Oversuggestible, -.03 and .12; Leader, -.03 and .06; Stuttering, -.05 (boys); Brother in penal detention, -.05 and -.03; Exclusion from school, -.08 and .08; Feeble-minded sibling, -.09 and -.08; Inattentive at school, -.10 and -.00; Question of encephalitis, -.10 and .01; Retardation in school, -.11 and -.12; Question of hypophrenia, -.16 and -.03

Omitted—Depressed, etc.

bi-serial correlations ranging from .29 to .35 with personality-total and conduct-total, but its tetrachoric correlations with police arrest were practically zero.

Its largest correlations (in the .40's) were with depressed mood or spells and inferiority feelings among boys, the corresponding coefficients for girls being of lesser size— $.33 \pm .08$  and  $.25 \pm .08$  respectively.

Three personality problems—sensitiveness over some specific fact or episode, daydreaming, and seclusiveness—yielded substantial correlations ranging from .28 to .38 among both sexes. Among girls three notations—repressed manner, sullenness, and swearing or bad language (undifferentiated)—yielded substantial correlations in the .30's and among boys moderate correlations in the .20's. Among girls an additional four behavior traits yielded substantial correlations in the .30's, but low coefficients below .20 among boys: queer behavior, sulkiness, irresponsibility, and contrariness.

Unhappiness showed moderate correlations in the .20's among both sexes with sensitiveness in general and incorrigibility. Two notations, for which only the girls' coefficients were computed—overinterest in the opposite sex and victim of sex abuse by older child or person—also showed moderate correlations in the .20's. Twelve miscellaneous case-record notations showed moderate correlations in the .20's among boys but low positive coefficients below .20 among girls: question of change of personality, lack of interest in school, inefficiency in work, play, etc., laziness, hatred or jealousy of sibling, restlessness, temper display, bad companions, staying out late at night, truancy from home, nail-biting, and discord between parents. Fourteen miscellaneous notations showed moderate correlations in the .20's among girls but low positive coefficients below .20 among boys: crying spells, changeable moods or attitudes, mental conflict, excuse-forming attitude, apprehensiveness, boastful or "show-off" manner, bossy manner, rudeness, disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), leading others into bad conduct, fighting or quarrelsomeness (including violence, undifferentiated), masturbation, overinterest in sex matters, and underweight condition.

Unhappiness showed three negative correlations of moderate size in the .20's, all among girls: lack of initiative, loitering or wandering, and refusal to attend school.

Among the six sex notations unhappiness showed four corre-

lations of moderate size in the .20's, all among girls: masturbation, overinterest in sex matters, overinterest in the opposite sex, and victim of sex abuse by older child or person.

Among the seven physical or psychophysical notations the only correlation of significant size was with underweight condition among girls,  $.20 \pm .06$ .

Among the four home or familial notations the only correlation of significant size was with unhappiness was for discord between parents among boys,  $.23 \pm .04$ .

When our cases showing a notation of either depressed mood or spells or unhappiness were grouped together under one rubric or combined into a broad grouping,<sup>2</sup> there were 219 such cases, or 10.4 per cent, among our 2,113 White boys and 125 cases, or 10.6 per cent, among our 1,181 White girls. The resulting correlations, as shown in Table 13, were not greatly different from those found when such notation was discussed separately.

Yielding substantial to large correlations ranging from about .20 to .47 for both notations and among both sexes were the following: sensitiveness or worrisomeness (undifferentiated), inferiority feelings, daydreaming, seclusiveness, hatred or jealousy of sibling, and question of change of personality. Six notations yielded substantial correlations with depressed mood or spells but moderate or low correlations with unhappiness: psychoneurotic trends, mental conflict, unpopularity, changeable moods or attitudes, restlessness, and inefficiency in work, play, etc. On the other hand, four notations showed meaningful correlations with unhappiness but were negligibly associated with depressed mood or spells: repressed manner, sullenness, incorrigibility, and swearing or bad language (undifferentiated).

Crying spells or crying easily was found among 473 boys, or 22.4 per cent, and among 297 girls, or 25.1 per cent, and is thus one of the most frequently appearing case-record notations found among the children studied in our clinic,<sup>3</sup> especially among

<sup>2</sup>The reasons for this grouping were given in I, 44 and 86, Table 13, Item J.

<sup>3</sup>I, 46.

## Other Correlations (Positive to Negative)

Overinterest in sex matters, .19 and .12; Mental conflict, .18 and .19; Stealing, .16 and .15; Temper display, .16 and .15; Disobedient, .14 and .13; Enuresis, .14 and .17; Swearing (general), .14 (boys); Neurological defect, .14 and .14; Grouped: disobedient, etc., .14 and .16; Refusal to attend school, .13 and .00; Masturbation, .13 and .15; Former convulsions, .13 and .11; Grouped: lack of interest in school, etc., .13 and .09; Contrary, .12 and .12; Destructive, .12 and .13; Fighting, .12 and .13; Lack of interest in school, .12 and .10; Stubborn, .12 and .15; Absent-minded, .12 and .18; Lues, .12 and .01; In-corrigeable, .11 and .10; Stuttering, .11 (boys); Defiant, .10 and .19; Truancy from school, .10 and .07; Preference for younger children, .10 and .16; Poor work in school, .10 and .08; Discord between parents, .10 and -.01; Lying, .09 and .16; Slovenly, .09 and .11; Excuse-forming, .09 and .19; Seclusive, .09 and .16; Loitering, .08 and -.01; Staying out late at night, .08 and .11; Threatening violence, .08 (boys); Truancy from home, .08 and .03; Listless, .08 and .09; Grouped: dull, slow, etc., .08 and -.02; Bad companions, .07 and .12; Inattentive in school, .07 and -.01; Underweight, .07 and .08; Speech defect, .07 and .03; Lazy, .06 and .03; Smoking, .06 (boys); Attractive manner, .06 and .10; Teasing other children, .05 (boys); Sex delinquency (coitus), .05 and -.05; Slow, dull, .05 and .01; Egocentric, .05 and .19; Lack of initiative, .05 and -.04; Oversuggestible, .05 and .15; Repressed, .05 and .15; Popular, .05 and .09; Exclusion from school, .04 and .15; Leader, .04 and .19; Boastful, "show-off," .03 and .17; Clean, .03 and .06; Overinterest in opposite sex, .03 (girls); Gang, -.01 (boys); Retardation in school, -.01 and -.09; Question of hypophrenia, -.04 and .06; Vocational guidance, -.05 and -.08; Immoral home conditions, -.05 and -.06; Irregular attendance at school, -.06 and -.08; Vicious home conditions, -.06 and -.10; Victim of sex abuse, -.06 (girls); Feeble-minded sibling, -.14 and -.13; Brother in penal detention, -.16 and -.18

Its highest correlations were with sensitiveness in general, the coefficients being  $.43 \pm .03$  and  $.50 \pm .04$  among boys and girls respectively. Its next highest correlation was with the notation "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated) with corresponding coefficients of  $.32 \pm .02$  and  $.47 \pm .03$  for boys and girls.

Three additional behavior traits yielded substantial correlations in the .30's among both sexes: sensitiveness over some specific fact or episode, question of change of personality, and temper tantrums or display (including irritable temperament, undifferentiated). Among girls five notations yielded substantial correlations in the .30's and among boys moderate coefficients in the .20's: depressed mood or spells, emotional instability, apprehensiveness, unpopularity, and question of encephalitis. An additional four behavior problems among girls yielded substantial correlations in the .30's but low coefficients below .20 among boys: quarrelsomeness, irregular sleep habits, restlessness, and fantastical lying.

Crying spells showed moderate correlations ranging from .19 to .26 among both sexes for the six behavior notations, worry over some specific fact or episode, sulkiness, inefficiency in work, play, etc., bashfulness, nail-biting, and "follower" and also for the notation complaining of bad treatment by other children, which was calculated only for boys. Among girls the following twenty-one miscellaneous notations showed moderate correlations in the .20's but among boys low positive coefficients below .20: unhappiness, inferiority feelings, staff notation of psychoneurotic trends, daydreaming, queer behavior, sullenness, "spoiled child," finicky food habits, hatred or jealousy of sibling, object of teasing by other children, distractibility, irresponsibility, disturbing influence in school, rudeness, leading others into bad conduct, violence, swearing or bad language (undifferentiated), egocentricity or selfishness (undifferentiated), restlessness in sleep, staff notation of unfavorable conduct prognosis, and headaches.

Among the six sex notations the only significant correlation with crying spells was for sex misbehavior denied entirely among boys,  $.24 \pm .04$ .

Among the seven physical or psychophysical notations the only significant correlations were with question of encephalitis,

the respective coefficients for boys and girls being  $.26 \pm .05$  and  $.32 \pm .06$ .

Among the four home or familial notations all correlations with crying spells were low or negligible.

## CHAPTER XV

### SENSITIVENESS AND WORRISOMENESS

Sensitiveness or worrisomeness, whether considered as a general habit of mind or as a concern over a specific fact or episode, appeared frequently among our clinical cases. About 23 per cent of our 2,113 White boys and about 22 per cent of our 1,181 White girls were so described. Curiously enough, the trait was remarked slightly more often among boys than among girls. In general the notations were correlated substantially with personality problems and occasionally also with conduct problems. With police arrest, however, the correlations were substantially zero, except that among girls the specific notation sensitiveness (general) showed a significant negative tetrachoric correlation of  $-.25 \pm .05$ . These case notations should, however, be considered of definite clinical importance, especially from the standpoint of personality deviation. The four tables of this chapter comprise different aspects of this general behavior trait.

Sensitiveness as a general trait was noted in about 8 per cent of our children. Its highest correlations (Table 15) were among girls, the tetrachoric coefficients ranging from .43 to .50 for crying spells, depressed mood or spells, and inferiority feelings, with substantial correlations also among boys. The highest correlation among boys was also for crying spells (.43  $\pm$  .03).

Among both sexes the following yielded substantial correlations in the .30's: sensitiveness over specific fact, changeable moods, and finicky or capricious food habits. Other meaningful correlations among both sexes were for psychoneurotic trends, seclusiveness, and for "nervousness" or restlessness (undifferentiated) with coefficients ranging from .25 to .36. Among girls the following additional notations yielded substantial correlations ranging from .30 to .37, while the boys' correlations were of doubtful significance though of positive sign: sulkiness, hatred or jealousy of sibling, boastful or "show-off" manner, and irregular sleep habits.

## Other Correlations (Positive to Negative)

Object of teasing, .19 and .18; Mental conflict, .19 and .09; Selfish, .18 and .17; Lack of interest in school, .17 and .02; Temper tantrums, .17 and .15; Complaining of bad treatment by other children, .16 (boys); Apprehensive, .15 and .05; Unpopular, .15 and -.01; Grouped: temper, etc., .14 and .18; Question of change of personality, .14 and .13; Overinterest in sex matters, .14 and .10; Lazy, .13 and .10; Former convulsions, .13 and .09; Neurological defect, .12 and .09; Stuttering, .12 (boys); Disobedient, .11 and .12; Restless, .13 and .13; Grouped: lack of interest in school, etc., .11 and .04; Question of encephalitis, .10 and .15; Quarrelsome, .10 and .18; Smoking, .10 (boys); Enuresis, .09 and .14; Nail-biting, .09 and .11; Refusal to attend school, .09 and .13; Emotional instability, .09 and .13; Preference for younger children, .09 and .12; Poor work in school, .09 and .09; Vocational guidance, .09 and .10; Headaches, .08 and .12; Masturbation, .08 and .06; Stubborn, .07 and .17; Irregular attendance at school, .07 and .04; Immoral home conditions, .07 and -.17; Grouped: dull, slow, etc., .06 and .07; Grouped: disobedient, etc., .06 and .10; Discord between parents, .06 and -.02; Lying, .05 and .01; Sex denied entirely, .05 and .18; Vicious home conditions, .05 and -.07; Grouped: fighting, etc., .05 and .14; Defiant, .03 and .13; Disturbing influence in school, .03 and .06; Lues, .03 and -.08; Fighting, .02 and .09; Inattentive in school, .01 and .04; Listless, .01 and .05; Distractible, .01 and .14; Oversuggestible, .01 and .10; Grouped: swearing, etc., .01 and -.09; Gang, .00 (boys); Rude, .00 and .16; Irresponsible, -.00 and .06; Slowly, -.01 and .04; Teasing other children, -.02 (boys); Stealing, -.02 and -.06; Swearing (general), -.02 (boys); Sex delinquency (coitus), -.02 and -.18; Slow, dull, -.02 and .02; Follower, -.03 and .03; Violence, -.03 and .05; Threatening violence, -.03 (boys); Loitering, -.03 and -.05; Destructive, -.03 and -.08; Temper display, -.04 and .05; Exclusion from school, -.04 and .02; Question of hypophrenia, -.05 and -.08; Incurrigible, -.06 and -.06; Overinterest in opposite sex, -.06 (girls); Leader, -.07 and .05; Underweight, -.07 and .07; Truancy from school, -.08 and .05; Conduct prognosis bad, -.10 and -.17; Bad companions, -.10 and .04; Retardation in school, -.12 and -.14; Feeble-minded sibling, -.12 and -.18; Leading others into bad conduct, -.14 and .01; Victim of sex abuse, -.14 (girls); Staying out late at night, -.15 and -.05

Omitted—Grouped: sensitive or worrisome, etc.

The following showed moderate correlations of .20 to .29 among both sexes: worry over specific fact or episode, unhappiness, bossy manner, inefficiency in work, play, etc., "spoiled child," and clean habits or appearance. Four notations showed moderate correlations ranging from .20 to .27 among boys, with lesser though positive correlations among girls: lack of initiative,

restlessness in sleep, attractive manner, and speech defect (other than stuttering). Among girls there were a dozen correlations ranging from .20 to .27, the corresponding coefficients for boys ranging only from .02 to .19; these were for irritable manner or disposition, excuse-forming attitude, contrariness, sullenness, egocentricity, queer behavior, fantastical lying, daydreaming, repressed manner, bashfulness, absent-mindedness, and popularity.

Only two significant negative correlations with sensitiveness (general) were found. Among girls the correlations for brother in penal detention was  $-.31 \pm .06$  and for truancy from home  $-.25 \pm .05$ , the boys' correlations being negligible.

For the six sex notations all coefficients were of almost negligible size. The largest were among girls: a negative correlation of  $-.18$  for sex delinquency (coitus) and a positive one of  $.18$  for sex misbehavior denied entirely. Since our cases were too few to establish "statistical significance" in case of tetrachoric correlations of less than  $\pm .20$ , one can report these coefficients only as suggesting that sexually abstinent girls tend to be sensitive, while sexually delinquent ones tend to be less sensitive in general than others.

Discord between parents and enuresis showed quite negligible correlations with sensitiveness (general).

Sensitiveness over some specific fact or episode appeared almost twice as often among our cases as sensitiveness in general. It was noted in 15 per cent of our 2,113 boys and in 13 per cent of our 1,181 girls and was one of the most frequent notations in the personality field.

The usual sources of this specialized sensitiveness were in order of frequency: school problems such as poor work in school, retardation in school, being in "ungraded room" or in room with younger or smaller children, special educational defect, exclusion from school because of poor work in studies, low intelligence, memory defect, etc.; physical deficiencies such as poor physique, short stature, loss of limb, crippled condition, obesity, convulsive attacks, wearing glasses, deafness or hearing defect, speech defect or stuttering, unattractive personal appearance or poor complexion, enuresis or bowel incontinence, etc.; sex misbehavior such as masturbation, sexual intercourse, homosexual behavior,

illegitimate pregnancy, and, among girls, menstruation; home or familial conditions such as the fact that relatives do not visit or write to patient or that he has no relatives, death of parent or near-relative, rejection or desertion by both parents or the fact of adoption or other circumstances concerning patient's parentage, poor clothing, poor financial condition of family or of self or the fact that the family receives aid from charity organizations, parent's criminality, immorality, alcoholism, viciousness, venereal disease, etc., and discord between parents or foster-parents; and miscellaneous source such as misdeeds in general, unpopularity or inability to make friends or sensitiveness over being an object of teasing by other children, race or nativity, and religion.<sup>1</sup>

Its correlations (Table 16) were very similar to those for sensitiveness in general. Its three highest correlations among both sexes were for inferiority feelings, mental conflict, and depressed spells or unhappiness (undifferentiated), the tetrachoric coefficients ranging from .41 to .50. Four personality traits showing coefficients ranging from .30 to .41 among both sexes were: unhappiness, sensitiveness in general, crying spells, and object of teasing by other children. The notations daydreaming and hatred or jealousy of sibling showed correlations in the .30's for girls and in the .20's for boys.

Seven traits showed moderate correlations in the .20's for both sexes: worry over some specific fact or episode, masturbation, overinterest in sex matters, psychoneurotic trends, bashfulness, seclusiveness, and probably "spoiled child." Among boys enuresis, repressed manner, attractive manner, and clean habits showed correlations ranging from .20 to .23 and lesser though positive correlations among girls. Eighteen notations showed correlations among girls ranging from .20 to .30 but lesser though generally positive coefficients among boys: emotional instability, changeable moods, queer behavior, "nervousness" or restlessness (undifferentiated), unpopularity, preference for younger children as playmates, irresponsibility, lack of interest in school, egocentricity, selfishness, bossy manner, stubbornness, defiant attitude,

## Other Correlations (Positive to Negative)

Headaches, .18 and .17; Complaining of bad treatment by other children, .18 (boys); Victim of sex abuse, .18 (girls); Question of change of personality, .17 and .19; Irregular sleep habits, .17 and .17; Lack of initiative, .17 and -.19; Speech defect, .17 and .07; Discord between parents, .17 and .07; Lazy, .16 and -.01; Sulky, .16 and .15; Listless, .15 and .01; Inefficient in work, play, etc., .14 and .18; Apprehensive, .14 and .07; Boastful, "show-off," .13 and .11; Rude, .13 and .01; Staying out late at night, .13 and .03; Sex delinquency (coitus), .13 and .01; Grouped: disobedient, etc., .13 and .13; Teasing other children, .12 (boys); Absent-minded, .12 and .10; Popular, .12 and .00; Underweight, .12 and .10; Grouped: lack of interest in school, etc., .12 and .18; Finicky food habits, .11 and .05; Listless, .11 and .09; Leader, .11 and .11; Nail-biting, .10 and .17; Temper display, .10 and .07; Conduct prognosis bad, .10 and -.08; Stuttering, .10 (boys); Question of encephalitis, .10 and .11; Vocational guidance, .10 and -.10; Sullen, .09 and .17; Temper tantrums, .09 and .16; Gang, .08 (boys); Distractible, .08 and .05; Grouped: temper, etc., .08 and .09; disobedient, .07 and .04; Irritable, .07 and .02; Sex denied entirely, .07 and .11; Poor work in school, .07 and .07; Immoral home conditions, .07 and .15; Grouped: swearing, etc., .07 and .15; Bad companions, .06 and .11; Refusal to attend school, .06 and .19; Smoking, .06 (boys); Contrary, .05 and .01; Threatening violence, .05 (boys); Restless in sleep, .05 and .14; Grouped: dull, slow, etc., .05 and -.05; Overinterest in opposite sex, .05 (girls); In-correctible, .04 and .09; Quarrelsome, .04 and .16; Truancy from home, .04 and .05; Vicious home conditions, .04 and -.00; Swearing (general), .03 (boys); Violence, .02 and .14; Destructive, .01 and .11; Loitering, .01 and -.13; Slovenly, .01 and .06; Truancy from school, .01 and .16; Follower, .01 and .06; Oversuggestible, .01 and .02; Disturbing influence in school, -.00 and .10; Inattentive in school, -.00 and .09; Fantastical lying, -.01 and .12; Excuse-forming, -.01 and .14; Exclusion from school, -.01 and .11; Irregular attendance at school, -.01 and .04; Slow, dull, -.04 and -.02; Lues, -.04 and .02; Fighting, -.05 and .11; Brother in penal detention, -.08 and .04; Feeble-minded sibling, -.13 and -.19; Question of hypophrenia, -.16 and -.08

Omitted—Grouped: sensitive or worrisome, etc.

fighting, stealing, lying, leading others into bad conduct, and neurological defect (unspecified).

Only one "statistically significant" negative coefficient was found, retardation in school, with values of -.14 and -.28 ± .04 for boys and girls respectively.

Boys appeared to be somewhat sensitive over enuresis (present or former), the tetrachoric  $r$  being  $.22 \pm .03$ , but seemingly do not worry about it. It does not appear to be associated with sensitiveness in general, however. Our girls seemed quite unconcerned over bed-wetting, though it was noted among 21 per cent of them.

Among the sex notations, two showed moderate correlations in the .20's among both sexes: masturbation and overinterest in sex matters. For victim of sex abuse by older person the correlation of .18 (calculated for girls only) may be suggestive but is scarcely "statistically significant" upon our small number of cases. For sex delinquency (coitus), overinterest in opposite sex (calculated for girls only), and sex misbehavior denied entirely, the correlations were of negligible size though positive in sign.

Although a great variety of conditions in the child's life served as sources of its concern or sensitiveness (vide supra), in many instances the presence of such conditions seemed only slightly associated with sensitiveness over some specific fact, e.g., poor work in school, exclusion from school, underweight condition, speech defect, stuttering (calculated for boys only), police arrest, immoral home conditions, vicious home conditions, brother in penal detention, and discord between parents. Some tendency toward a moderate association was shown by the following potential sources (with their respective coefficients for boys and girls): neurological defect (unspecified) (.10 and  $.23 \pm .05$ ), misdeeds as measured by conduct-total (.19  $\pm$  .02 and  $.27 \pm .03$ ), and unpopularity (.09 and  $.20 \pm .07$ ).

Among boys the significant correlations with sensitiveness over some specific fact or episode were found only in the case of personality difficulties, but among girls there were also a number of moderate correlations with conduct problems as well as with personality problems.

Worry over some specific fact or episode was noted slightly more often among our boys than among the girls, the percentages of incidence being 4.7 and 3.4 respectively. The usual sources of this worrisomeness were, in order of frequency: sex misbehavior (masturbation, homosexual behavior, sexual intercourse, illegitimate pregnancy), physical deficiencies (poor health, short stature,

etc., unattractive personal appearance and poor complexion), poor health or insanity of parent, foster-parent, or guardian, race or nativity, religion, low intelligence, memory defect, deafness or hearing defect, "feelings of guilt," "castration complex," and "stool hypochondriasis."<sup>2</sup> Like sensitiveness in general and sensitiveness over some specific fact, it showed many substantial correlations with other personality problems among both sexes and among girls with a number of conduct problems also. It should be considered a significant symptom from a clinical standpoint. With police arrest, however, its associations were practically zero.

The highest correlations for worry over some specific fact or episode (Table 17) were with mental conflict, the coefficients being  $.49 \pm .06$  and  $.50 \pm .09$  for boys and girls respectively. Other substantial correlations ranging from .33 to .44 for either sex were for psychoneurotic trends, depressed spells or unhappiness (undifferentiated), inferiority feelings, and among girls overinterest in sex matters, masturbation, seclusiveness, and clean habits.

Seven notations showing moderate correlations in the .20's for both sexes were sensitiveness (general), sensitiveness over specific fact, crying spells, "nervousness" or restlessness (undifferentiated), irregular sleep habits, daydreaming, and attractive manner. A few notations showed moderate correlations in the .20's for boys but negligible correlations for the girls: apprehensiveness, bashfulness, object of teasing by other children, violent home conditions, and (calculated for boys only) teasing other children. Seventeen personality and conduct difficulties showed moderate correlations ranging from .20 to .34 among our girls but lesser or even negligible correlations among the boys: truancy from school, exclusion from school, associating with bad companions, violence, destructiveness, stubbornness, defiant attitude, leading others into bad conduct, sulkiness, bossy manner, unpopularity, hatred or jealousy of sibling, changeable moods, question of change of personality, queer behavior, distractibility, and finicky food habits. Similar differences between the boys' and girls' cases were shown for headaches, neurological defect, and question of encephalitis. Preference for younger children as playmates showed

## Other Correlations (Positive to Negative)

Fantastical lying, .19 and .11; Egocentric, .19 and .18; Grouped: ego-centric, etc., .19 and .15; Sex delinquency (coitus), .18 and .15; Complaining of bad treatment by other children, .18 (boys); Irritable, .17 and .17; Restless in sleep, .17 and .12; Discord between parents, .17 and .05; Absent-minded, .16 and .11; Emotional instability, .16 and .14; Spoiled child, .16 and .19; Unhappy, .16 and -.04; Boastful, "show-off," .15 and .11; Lack of initiative, .15 and -.15; Inefficient in work, play, etc., .14 and .16; Selfish, .14 and .12; Grouped: lack of interest in school, etc., .14 and .10; Inattentive in school, .14 and .18; Grouped: dull, slow, etc., .13 and -.17; Victim of sex abuse, .13 (girls); Grouped: temper, etc., .12 and .17; Nail-biting, .11 and .16; Refusal to attend school, .10 and .03; Temper display, .10 and .03; Excuse-forming, .10 and .04; Grouped: swearing, etc., .10 and .19; Contrary, .09 and .03; Enuresis, .09 and .09; Quarrelsome, .09 and -.01; Leader, .09 and .05; Immoral home conditions, .09 and -.03; Overinterest in opposite sex, .09 (girls); Lack of interest in school, .08 and .01; Follower, .07 and -.04; Poor work in school, .07 and -.03; Irregular attendance at school, .07 and .15; Underweight, .06 and .16; Lying, .05 and .12; Rude, .05 and .07; Slow, dull, .05 and .07; Repressed, .05 and .18; Former convulsions, .05 and .03; Smoking, .04 (boys); Grouped: fighting, etc., .04 and .07; Disobedient, .03 and .13; Disturbing influence in school, -.00 and .17; Threatening violence, -.00 (boys); Fighting, -.01 and .10; Loitering, -.01 and .16; Vocational guidance, -.01 and .13; Stealing, -.03 and .10; Sullen, -.03 and -.04; Conduct prognosis bad, -.03 and -.00; Grouped: disobedient, etc., -.03 and .10; Incurable, -.04 and .03; Sex denied entirely, -.04 and -.09; Lues, -.04 and .01; Lazy, -.05 and -.00; Slovenly, -.05 and .02; Oversuggestible, -.05 and .15; Temper tantrums, -.07 and .11; Speech defect, -.07 and .09; Gang, -.08 (boys); Truancy from home, -.10 and -.02; Swearing (general), -.11 (boys); Stuttering, -.15 (boys); Staying out late at night, -.16 and .02

Omitted—Grouped: sensitive or worrisome, etc.

the small positive correlation of  $.22 \pm .09$  among girls but the negative correlation of  $-.24 \pm .06$  among boys.

There were several significant negative correlations. Retardation in school among both sexes yielded the substantial negative correlations of  $-.36 \pm .04$  and  $-.34 \pm .05$  among boys and girls respectively. Question of hypophrenia showed negative correlations of  $-.23 \pm .04$  and  $-.10$  for boys and girls respectively. The four notations brother in penal detention, feeble-minded sibling, listlessness, and popularity showed moderate negative correlations ranging from  $-.20$  to  $-.26$  among girls but lesser or negligible correlations among boys.

Sex difficulties appear to be slightly associated with worry over some specific fact or episode.

When the children with one or more notations of sensitive-ness (general), sensitiveness over some specific fact, and worry over some specific fact (together with a handful of cases in which the notation of worrisomeness in general occurred too infrequently to justify separate statistical treatment) were combined into one group, there were 490 boys and 255 girls so described. The correlations for sensitiveness or worrisomeness (thus undifferentiated), as shown in Table 18, were usually larger than the corresponding

Omitted—Sensitive (general); Sensitive over specific fact; Worry over specific fact

correlations for each of the three traits when considered separately. This fact, together with the tendency for high interrelation among these three notations, indicates their close similarity.

The bi-serial correlations with the personality-total for both boys and girls were relatively high,  $.43 \pm .02$  and  $.50 \pm .02$  respectively. For the conduct-total the correlation for girls was substantial,  $.28 \pm .03$ , but relatively low among the boys,  $.16 \pm .02$ . Their significance from a clinical standpoint is thus established, but from the sheer standpoint of "juvenile delinquency" their importance is slight in view of their generally negligible correlations with police arrest.

The highest correlations for sensitiveness or worrisomeness (undifferentiated) were for mental conflict, inferiority feelings, depressed spells or unhappiness (undifferentiated), and crying spells, with correlations ranging from  $.52 \pm .03$  down to  $.40 \pm .03$ . Psychoneurotic trends yielded substantial correlations of  $.39 \pm .04$  and  $.35 \pm .05$  for boys and girls respectively. The following five personality traits showed correlations ranging from .30 to .37

among girls, and coefficients in the .20's for boys: object of teasing by other children, hatred or jealousy of sibling, changeable moods, "nervousness" or worrisomeness (undifferentiated), and daydreaming. In addition, three notations, bossy manner, emotional instability, and sulkiness, yielded tetrachoric correlations ranging from .30 to .32 among girls but among boys lower correlations ranging from .11 to .19.

The following personality notations showed moderate correlations in the .20's for both boys and girls: masturbation, overinterest in sex matters, seclusiveness, bashfulness, inefficiency in work, play, etc., clean habits, "spoiled child," and (calculated for boys only) complaining of bad treatment by other children. The three notations finicky food habits, lack of initiative, and attractive manner among boys showed moderate correlations of .22 to .25 but lower or negligible correlations among girls. The following seventeen personality, conduct, and other notations among our girls showed moderate correlations in the .20's but low or negligible correlations among the boys: repressed manner, queer behavior, sullenness, question of change of personality, egocentricity, selfishness, defiant attitude, fighting or quarrelsomeness (undifferentiated), truancy from school, leading others into bad conduct, excuse-forming attitude, restlessness, irregular sleep habits, restlessness in sleep, preference for younger children as playmates, headaches, and neurological defect (unspecified).

Two notations showed significant negative correlations among girls: retardation in school ( $-.28 \pm .03$ ) and feeble-minded sibling ( $-.21 \pm .05$ ). the corresponding coefficients for boys also being negative ( $-.17$  and  $-.16$  respectively).

Among the six sex notations studied, only two—masturbation and overinterest in sex matters—showed significant correlations with sensitiveness or worrisomeness (undifferentiated). The correlations for sex delinquency (coitus), sex misbehavior denied entirely, and the two notations which were calculated for girls only—victim of sex abuse and overinterest in opposite sex—showed negligible correlations of positive sign.

Physical or constitutional defects such as underweight condition, speech defect and stuttering, former convulsions, lues, question of encephalitis, and enuresis showed only moderate or low positive correlations, while neurological defect (unspecified)

among girls showed the moderate positive correlation of  $.23 \pm .05$ .

Unfavorable home conditions such as discord between parents, vicious or immoral home conditions, and brother in penal detention showed negligible association with sensitiveness or worrisomeness (undifferentiated).

CHAPTER XVI

BASHFULNESS AND APPREHENSIVENESS

The case notations of bashfulness and apprehensiveness appeared from the data of this chapter to be of quite minor clinical importance as far as our three criteria of "seriousness" are concerned. In fact, among girls the negative tetrachoric correlation of  $-.28 \pm .04$  indicates that bashful girls are less likely to be involved in "juvenile delinquency" than their less bashful sisters.

Bashfulness, shyness, or becoming embarrassed easily, etc., was a frequently appearing item among our cases. It was noted among 316 of our 2,113 White boys and among 218 of our 1,181 White girls, the respective percentages being 15.0 and 18.5.

Its highest correlations were of barely substantial size in the .30's: inferiority feelings and seclusiveness among girls and apprehensiveness among boys, the corresponding coefficients for the other sex being of moderate size in the .20's (Table 19).

## Other Correlations (Positive to Negative)

Queer, .19 and .07; Underweight, .19 and .16; Grouped: dull, slow, etc., .18 and .14; Preference for younger children, .18 and .08; Vocational guidance, .16 and .09; Spoiled child, .16 and -.05; Unpopular, .16 and -.08; Irritable, .16 and .08; Lazy, .16 and -.07; Hatred or jealousy of sibling, .15 and .04; Clean, .15 and .03; Speech defect, .15 and .02; Restless in sleep, .14 and .08; Daydreaming, .14 and .16; Teasing other children, .14 (boys); Repressed, .13 and .14; Grouped: depressed, etc., .13 and .12; Unhappy, .12 and .08; Stubborn, .12 and -.03; Feeble-minded sibling, .12 and .02; Selfish, .11 and .11; Depressed, .11 and .14; "Nervous," .11 and .10; Mental conflict, .11 and .06; Poor work in school, .11 and .06; Neurological defect, .11 and .05; Slow, dull, .10 and .07; Lack of interest in school, .09 and .05; Grouped: "nervous," etc., .09 and .08; Oversuggestible, .08 and .00; Absent-minded, .08 and -.03; Masturbation, .08 and -.07; Inefficient in work, play, etc., .08 and .02; Finicky food habits, .07 and .14; Question of change of personality, .07 and -.03; Distractible, .07 and -.04; Question of hypochondria, .07 and .10; Headaches, .07 and .02; Discord between parents, .07 and .11; Grouped: lack of interest in school, etc., .06 and .04; Grouped: temper, etc., .06 and .00; Immoral home conditions, .06 and -.04; Stuttering, .06 (boys); Object of teasing, .06 and .07; Sulky, .06 and .06; Enuresis, .05 and .02; Conduct prognosis bad, .05 and -.07; Popular, .05 and .06; Vicious home conditions, .04 and -.05; Changeable moods, .04 and .07; Nail-biting, .04 and .01; Bossy, .04 and -.04; Sullen, .03 and -.05; Leader, .03 and -.08; Irregular attendance at school, .02 and -.06; Lues, .02 and .13; Attractive manner, .02 and .10; Inattentive in school, .02 and -.02; Irresponsible, .01 and -.03; Slovenly, .01 and .03; Grouped: egocentric, etc., .01 and -.03; Psychoneurotic, .00 and .16; Quarrelsome, .00 and -.03; Refusal to attend school, .00 and .00; Temper display, -.00 and .04; Leading others into bad conduct, -.01 and .04; Excuse-forming, -.02 and -.07; Egocentric, -.02 and -.10; Former convulsions, -.03 and .03; Complaining of bad treatment by other children, -.03 (boys); Temper tantrums, -.03 and -.12; Fantastical lying, -.03 and -.03; Boastful, "show-off," -.03 and .11; Destructive, -.04 and -.04; Grouped: disobedient, etc., -.04 and -.08; Retardation in school, -.05 and -.05; Restless, -.05 and -.05; Overinterest in sex matters, -.05 and .07; Threatening violence, -.05 (boys); Victim of sex abuse, -.05 (girls); Contrary, -.05 and -.09; Loitering, -.06 and -.18; Lying, -.06 and -.09; Brother in penal detention, -.06 and .04; Grouped: swearing, etc., -.07 and -.11; Bad companions, -.07 and -.11; Swearing (general), -.08 (boys); Emotional instability, -.08 and -.04; Sex delinquency (coitus), -.09 and -.19;

TABLE 19—Continued

Stealing, -.09 and -.13; Defiant, -.09 and .06; Overinterest in opposite sex, -.09 (girls); Incurable, -.10 and -.17; Staying out late at night, -.10 and -.13; Grouped: fighting, etc., -.10 and -.07; Violence, -.11 and .01; Disturbing influence in school, -.12 and -.06; Fighting, -.12 and -.11; Gang, -.12 (boys); Sex denied entirely, -.13 and -.07; Truancy from home, -.13 and .19; Disobedient, -.13 and -.06; Truancy from school, -.14 and -.04; Smoking, -.18 (boys)

The following personality problems showed moderate correlations in the .20's among both sexes: sensitiveness or worrisomeness (especially sensitiveness over specific fact), "follower," and crying spells. The three notations lack of initiative, listlessness, and worry over specific fact also showed moderate tetrachoric correlations in the .20's among boys but lesser or negligible correlations among girls.

Several minor negative correlations ranging from -.20 to -.22 were found: among boys for irregular sleep habits and exclusion from school and among girls for question of encephalitis and rudeness.

Among the six sex correlations the only one of probable significant size was the interesting negative one of  $-.19 \pm .04$  with sex delinquency (coitus) among girls, all other coefficients in this field being negligible.

It will be noted that whatever correlations existed with bashfulness were almost entirely confined to personality difficulties. Conduct problems showed only a negligible relationship.

A similar personality problem, apprehensiveness, which occurred in 322 of our boys and in 149 of our girls, showed a tendency for slightly larger correlation with other traits. Its highest correlations, as shown in Table 20, among both boys and girls were with bashfulness, crying spells, and "nervousness." The following nine notations showed moderate correlations ranging from .20 to .26 among boys but lesser or negligible correlations among girls: psychoneurotic trends, queer behavior, seclusiveness, repressed manner, worry over some specific fact, oversuggestibility, sulkiness, headaches, and (computed for boys only) teasing other children. The following behavior difficulties yielded moderate correlations ranging from .30 down to .20 among girls but less than

TABLE 20—Continued

Slow, dull, .10 and .08; Finicky food habits, .10 and .11; Nail-biting, .09 and .15; Masturbation, .09 and .10; Conduct prognosis bad, .09 and -.02; Attractive manner, .09 and -.02; Irregular attendance at school, .09 and -.03; Grouped: temper, etc., .09 and .08; Speech defect, .08 and -.06; Emotional instability, .08 and .16; Depressed, .08 and .09; Staying out late at night, .08 and .17; Destructive, .08 and .09; Daydreaming, .07 and .05; Poor work in school, .07 and .12; Underweight, .07 and .10; Clean, .06 and .11; Temper display, .06 and .02; Swearing (general), .06 (boys); Enuresis, .06 and .07; Inefficient in work, play, etc., .05 and .12; Irresponsible, .05 and .05; Rude, .05 and .14; Slowly, .05 and .08; Truancy from school, .05 and .19; Mental conflict, .05 and .18; Grouped: fighting, etc., .04 and .10; Grouped: disobedient, etc., .04 and .11; Retardation in school, .04 and -.04; Sullen, .04 and .10; Lazy, .04 and -.02; Inattentive in school, .03 and .13; Gang, .03 (boys); Temper tantrums, .03 and .17; Stuttering, .03 (boys); Loitering, .02 and .06; Boastful, "show-off," .02 and .18; Smoking, .01 (boys); Stubborn, .01 and -.01; Exclusion from school, .01 and .05; Discord between parents, .01 and .03; Vicious home conditions, .01 and .19; Popular, .00 and .12; Lues, -.00 and -.10; Restless, -.00 and .14; Overinterest in opposite sex, -.00 (girls); Fighting, -.01 and .06; Lying, -.01 and .12; Immoral home conditions, -.01 and -.06; Stealing, -.02 and .13; Incurable, -.02 and .08; Fantastical lying, -.02 and .08; Disturbing influence in school, -.02 and .19; Defiant, -.03 and .19; Threatening violence, -.03 (boys); Question of encephalitis, -.03 and .16; Brother in penal detention, -.03 and -.11; Truancy from home, -.05 and .14; Sex delinquency (coitus), -.05 and -.00; Leading others into bad conduct, -.06 and .14; Disobedient, -.08 and .06; Quarrelsome, -.08 and .08; Distractible, -.08 and .18; Selfish, -.09 and .09; Egocentric, -.10 and -.05; Grouped: egocentric, etc., -.10 and .01; Leader, -.11 and -.02; Feeble-minded sibling, -.14 and .11

.20 among boys: question of change of personality, unhappiness, irregular sleep habits, restlessness in sleep, lack of interest or inattentiveness in school (undifferentiated), inferiority feelings, unpopularity, "nervousness" or restlessness (undifferentiated), swearing or bad language (undifferentiated), bossy manner, and (computed for girls only) victim of sex abuse.

No significant negative correlations were found.

Sex notations, with the lone exception of victim of sex abuse, showed negligible correlations.

Apprehensiveness, like bashfulness, we may note in conclusion, showed a few moderate correlations with personality problems but almost no association with conduct problems.

## CHAPTER XVII

### STAFF NOTATIONS OF "INFERIORITY FEELINGS" AND "MENTAL CONFLICT"

The staff notations of inferiority feelings and mental conflict were among the most frequent of "diagnostic terms" employed in the clinical examination of our children. Among boys these two personality problems appeared to be fairly closely associated, as one may infer from their tetrachoric correlation of  $.53 \pm .04$ ; but among girls the association appeared to be only moderate, the correlation being  $.20 \pm .09$ . Both should be considered as relatively serious behavior problems from a clinical standpoint and in view of their substantial to high bi-serial correlations of .35 to .59 with the personality-total and their lesser though significant correlations of .25 to .40 with the conduct-total. From the standpoint of "juvenile delinquency," however, their importance appeared to be almost negligible, since the tetrachoric coefficients ranged only from  $-.02$  to  $.16$  with the fact of a police arrest or detention.

Staff notation or question of "inferiority" feeling or "complex," or feeling of inadequacy was found among 202 of our 2,113 White boys and 62 of our 1,181 White girls, the respective percentages being 9.6 and 5.2. Its incidence among boys is thus seen to be definitely larger than among girls.

Its highest correlation (Table 21) was  $.53 \pm .04$  among boys with mental conflict, in contrast with its scarcely significant correlation of  $.20 \pm .09$  among girls. Its other high correlations were for sensitiveness or worrisomeness (undifferentiated) and for sensitiveness over some specific fact with tetrachoric coefficients of .49 or .50. Unhappy appearance or manner among boys was associated to the very substantial extent of  $.43 \pm .05$  with inferiority feelings, but the coefficient of  $.25 \pm .08$  among girls was of only moderate significance. }

## Other Correlations (Positive to Negative)

Fantastical lying, .19 and .00; Disturbing influence in school, .19 and .18; Lack of interest in school, .18 and .11; Nail-biting, .18 and .13; Grouped: egocentric, etc., .18 and .11; Grouped: swearing, etc., .17 and -.04; Egocentric, .16 and .18; Stuttering, .16 (boys); Underweight, .15 and .09; Lack of initiative, .15 and .11; Sex delinquency (coitus), .15 and -.09; Enuresis, .15 and .10; Conduct prognosis bad, .14 and -.07; Clean, .14 and .10; Grouped: lack of interest in school, etc., .14 and .13; Threatening violence, .13 (boys); Selfish, .13 and .17; Leading others into bad conduct, .13 and .17; Destructive, .13 and .17; Teasing other children, .12 (boys); Emotional instability, .12 and .17; Attractive manner, .12 and .10; Grouped: disobedient, etc., .12 and .08; Disobedient, .10 and .04; Stealing, .10 and .07; Stubborn, .10 and .07; Exclusion from school, .10 and .08; Speech defect, .09 and .02; Excuse-forming, .09 and .17; Temper tantrums, .09 and .17; Sullen, .09 and -.13; Incurable, .09 and .06; Inattentive in school, .08 and .15; Preference for younger children, .08 and .05; Discord between parents, .08 and .08; Smoking, .07 (boys); Staying out late at night, .06 and .12; Oversuggestible, .05 and .09; Sulky, .05 and .09; Bad companions, .04 and -.01; Irresponsible, .04 and .13; Slovenly, .04 and .07; Grouped: dull, slow, etc., .03 and .05; Truancy from home, .03 and .02; Refusal to attend school, .02 and .18; Listless, .02 and .02; Immoral home conditions, .02 and -.01; Irregular attendance at school, .01 and -.01; Headaches, .01 and -.19; Question of encephalitis, .00 and .01; Leader, -.01 and .06; Follower, -.02 and .08; Truancy from school, -.02 and .06; Slow, dull, -.03 and -.01; Brother in penal detention, -.03 and -.14; Popular, -.04 and -.06; Sex denied entirely, -.04 and .04; Vocational guidance, -.06 and .15; Question of hypochondria, -.06 and -.07; Gang, -.07 (boys); Former convulsions, -.08 and .08; Overinterest in opposite sex, -.11 (girls); Victim of sex abuse, -.15 (girls); Lues, -.16 and .08

The following five personality difficulties among both sexes yielded substantial coefficients in the .30's: hatred or jealousy of sibling, depressed spells or unhappiness (undifferentiated), worry over some specific fact, daydreaming, and object of teasing by other children. Four personality traits yielded substantial correlations ranging from .43 down to .32 among girls but moderate coefficients in the .20's for boys: sensitiveness in general, depressed spells, seclusiveness, and bashfulness.

Five behavior problems yielded moderate correlations ranging from .20 to .29 among both sexes: unpopularity, queer behavior, boastful or "show-off" manner, quarrelsomeness, and lying. The following ten notations showed moderate correlations in the .20's among boys but lesser though positive ones among girls: laziness, "spoiled child," complaining of bad treatment by other children, psychoneurotic trends, bossy manner, rudeness, masturbation, temper display, question of change of personality, and (computed for boys only) swearing (general). A large list of twenty behavior and other notations showed moderate or substantial correlations ranging from .32 down to .20 among girls but low positive correlations below .20 among boys: "nervousness," irregular sleep habits, restlessness in sleep, irritable manner or disposition, restlessness (in general), changeable moods, fighting, defiant attitude, temper tantrums or temper display (undifferentiated), violence, crying spells, absent-mindedness, repressed manner, inefficiency in work, play, etc., distractibility, poor work in school, apprehensiveness, overinterest in sex matters, finicky food habits, and neurological defect (unspecified). The trait contrariness among girls showed the moderate correlation of  $.23 \pm .05$ , but among our 2,113 boys there were no instances whatever in which a "contrary" child also showed "inferiority feelings," and therefore a tetrachoric coefficient could not be calculated.

Four case-record notations showed negative correlations ranging from  $-.33$  to  $-.21$  among girls but negligible correlations among boys: feeble-minded sibling, vicious home conditions, loitering (including wandering or "bumming" on streetcars, etc., or loafing in poolrooms, dance halls, etc.), and retardation in school.

Among the six sex notations there were only two instances in which inferiority feelings showed statistically significant correlations in our data. These were for masturbation among boys

(.24  $\pm$  .03) and for overinterest in sex matters among girls (.22  $\pm$  .08).

Among physical and psychophysical deficiencies in our data, non-significant correlations were found for enuresis, underweight condition, and lues among both sexes. Neurological defect (unspecified) among girls yielded the moderate correlation of .22  $\pm$  .07. Speech defect and stuttering (undifferentiated) likewise appeared to be unassociated with inferiORITY feelings. These findings are contrary to general belief among clinic workers. Again we must point out that because of the paucity of data our results are presented as suggestive rather than as conclusive.

Question of hypophrenia (or suspected mental deficiency) and slow or dull manner yielded negligible negative correlations, but it will be recalled that intelligence quotient (IQ) yielded positive bi-serial correlations of .22  $\pm$  .02 and .18 among boys and girls respectively (see Table 10, p. 130). It appears, then, that intelligent children do not seem to suffer from inferiORITY feelings, while the less intelligent ones, whom one might suppose to be especially warranted in being so affected, actually seem no more affected than others. Poor work in school showed a moderate positive association, especially among girls, but retardation in school (defined to mean at least a prospective two years of retardation by the age of fourteen) showed an equally moderate negative relationship. Exclusion or suspension from school for any cause showed a negligible relationship. We may conclude that children in general do not develop an "inferiORITY" when their intelligence is low or their school achievement poor.

Unpopularity seemed to be a moderate cause of an "inferiORITY." Popularity showed corresponding correlations of negative sign.

(Among home conditions which would presumably give rise to "inferiORITIES" the only significant indication was the negative coefficient of -.27  $\pm$  .08 among girls for vicious home conditions. The three notations discord between parents, immoral home conditions, and brother in penal detention were quite unassociated with "inferiORITIES."

InferiORITY feelings are hardly productive of an excuse-forming attitude, since the low positive correlations of .09 and .17 can scarcely be considered as significant.

Staff notation of mental or emotional conflict or "complex" or marked emotional disturbance concerning certain subjects was employed as a diagnostic term in 102 of our boys and 45 of our girls, the respective percentages of incidence being 4.8 and 3.8.

Its highest correlations (Table 22) was with inferiority feelings, the tetrachoric coefficients for boys and girls, respectively, being  $.53 \pm .04$  and  $.20 \pm .09$ . In its correlations with

Nail-biting, .05 and .06; Teasing other children, .05 (boys); Apprehensive, .05 and .18; Leader, .05 and .08; Lues, .04 and .11; Truancy from school, .03 and .12; Speech defect, .03 and .03; Finicky food habits, .02 and -.07; Slow, dull, .02 and -.10; Defiant, .01 and .14; Staying out late at night, .01 and .13; Restless in sleep, .01 and .19; Underweight, .01 and .17; Oversuggestible, -.00 and .02; Smoking, -.01 (boys); Changeable moods, -.01 and .15; Distractible, -.05 and .09; Former convulsions, -.05 and .08; Question of encephalitis, -.09 and .18; Question of hypophrenia, -.10 and -.18; Irregular attendance at school, -.15 and -.15; Loitering, -.17 and -.17; Brother in penal detention, -.17 and -.15

other traits mental conflict showed many similarities to inferiority feelings.

Mental conflict yielded its highest tetrachoric correlations with sensitiveness or worrisomeness (undifferentiated), worry over specific fact, and sensitiveness over specific fact, the coefficients ranging from .46 to .52. Staff notation of psychoneurotic trends yielded the meaningful correlation of  $.39 \pm .06$  among boys and a low correlation of .19 among girls. Among girls the following five behavior problems showed substantial correlations ranging from .30 to .42 but among boys only moderate correlations in the .20's: overinterest in sex matters, depressed spells, queer behavior, absent-mindedness, and bossy manner. The following nine notations also showed substantial correlations in the .30's for girls but negligible correlations below .20 for boys: daydreaming, preference for younger children as playmates, destructiveness, violence, temper tantrums, leading others into bad conduct, exclusion from school, enuresis, and headaches.

The following six behavior difficulties showed moderate correlations in the .20's for both sexes: question of change of personality, repressed manner, seclusiveness, hatred or jealousy of sibling, masturbation, and sex delinquency (coitus). Stuttering (computed for boys only) showed a moderate correlation of  $.22 \pm .07$ . Two behavior problems among boys—boastfulness or "show-off" manner and lack of interest in school—showed correlations of  $.22 \pm .05$  and  $.20 \pm .05$  respectively but negligible correlations among girls. A large list of fifteen case notations showed moderate correlations in the .20's among the girls but low or negligible correlations among the boys: emotional instability, restlessness, unhappiness, "spoiled child", unpopularity, object of teasing by

other children, inattentiveness in school, inefficiency in work, play, etc., stealing, fantastical lying, swearing or bad language (undifferentiated), fighting, disobedience, stubbornness, and victim of sex abuse by older child or person.

Four significant negative correlations were found. Popularity among boys yielded the significant negative correlation of  $-.24 \pm .06$  with mental conflict but only  $.01$  among girls. Retardation in school, feeble-minded sibling, and temper display among girls yielded negative correlations ranging from  $-.26$  to  $-.36$ , the corresponding correlations for boys being zero or a negligible negative.

The staff notation of unfavorable conduct prognosis showed a zero correlation among boys, while among our 1,181 girls a tetrachoric correlation was not calculable since there were no instances in which a girl with mental conflict was so described.

Sex problems tended to be more significantly associated with mental conflict than with inferiority feelings. Among girls the tetrachoric correlation for overinterest in sex matters was very substantial,  $.42 \pm .08$ , the corresponding correlation for boys being only  $.20 \pm .07$ . Sex delinquency (coitus), masturbation, and (calculated only for girls) victim of sex abuse showed moderate correlations in the .20's. Sex misbehavior denied entirely (for both boys and girls) and overinterest in opposite sex (calculated for girls only) showed quite negligible correlations.

Enuresis, which showed no correlation with inferiority feelings, was correlated to the significant extent of  $.31 \pm .06$  among girls with mental conflict, though the corresponding coefficient for boys was practically zero. Underweight condition, speech defect, neurological defect, and lues were only negligibly correlated with mental conflict. Question of hypophrenia and retardation in school tended to be negatively associated with mental conflict, but intelligence quotient (IQ), as we have seen in Table 10 (p. 130), showed the moderate positive correlation of  $.23$  for both sexes with mental conflict.

The four undesirable home conditions—discord between parents, vicious home conditions, immoral home conditions, and brother in penal detention—were negligibly correlated with mental conflict.

We may conclude this chapter by noting that such personality problems as sensitiveness or worrisomeness, depressed or unhappy moods, queer, seclusive or absent-minded behavior, daydreaming, psychoneurotic trends, hatred or jealousy of sibling, object of teasing by other children and unpopularity and masturbation tended to be associated with both inferiority feelings and mental conflict but that children so affected do not assume a boastful or "show-off" manner as a compensatory mechanism. Among boys the positive correlations appeared to be almost entirely with personality problems, while among the girls there were many moderate correlations also with conduct problems.<sup>1</sup>

---

<sup>1</sup>A more extensive discussion of the correlations with staff notation of inferiority feelings (Table 21) may be found in the author's article "Inferiority Attitudes and Their Correlations among Children Examined in a Behavior Clinic," accepted for publication (1941) by the Journal of Genetic Psychology.

## CHAPTER XVIII

### PSYCHONEUROTIC TRENDS AND "SPOILED CHILD"

In spite of their supposed interdependence, psychoneurotic trends and "spoiled child" do not appear to be very closely related since the tetrachoric correlations between these traits were only  $.29 \pm .05$  and  $.08$  among boys and girls respectively. Their correlations with other behavior problems appeared in some cases to be similar but in other cases to be quite unlike.

Staff diagnosis or question of psychoneurosis or psychoneurotic or neurotic trends (unspecified), hysteria, neurasthenia, psychasthenia, etc., was noted in 87 of our 2,113 White boys and in 64 of our 1,181 White girls, the percentages of incidence being 4.1 and 5.4 respectively. It was one of the most frequently employed diagnostic terms found in the case records during the years in which these children were examined. This notation as used in the present chapter varied all the way from an unqualified psychiatric diagnosis down to a clinical description of a relatively minor personality trait. It was substantially correlated with personality-total but only moderately and irregularly associated with conduct-total or police arrest (Table 23).

The highest correlation with psychoneurotic trends was for emotional instability among girls,  $.47 \pm .06$ , the corresponding coefficient for boys being also substantial,  $.29 \pm .07$ .

The three personality problems—depressed spells, sensitiveness or worrisomeness (undifferentiated), and worry over some specific fact—yielded substantial to high correlations ranging from  $.35$  to  $.46$  among both sexes. Mental conflict among boys showed a very substantial correlation of  $.39 \pm .06$ , but among girls the coefficient was only  $.19$ . The vague notation "nervousness" showed substantial correlations of  $.33$  to  $.35$  among both sexes.

Three important personality difficulties yielded substantial correlations ranging from  $.38$  down to  $.32$  among girls but moderate coefficients in the  $.20$ 's for the boys: question of change

Other Correlations (Positive to Negative)

Headaches, .19 and .16; Immoral home conditions, .19 and .02; Overinterest in opposite sex, .19 (girls); Hatred or jealousy of sibling, .18 and .18; Sex delinquency (coitus), .17 and -.05; Listless, .17 and .15; Disobedient, .15 and .16; Grouped: fighting, etc., .14 and .08; Refusal to attend school, .14 and .04; Daydreaming, .12 and .13; Quarrelsome, .11 and .14; Object of teasing, .11 and .05; Grouped: disobedient, etc., .10 and .12; Unhappy, .10 and .04; Nail-biting, .10 and -.01; Complaining of bad treatment by other children, .09 (boys); Sex denied entirely, .08 and -.05; Enuresis, .07 and -.07; Question of encephalitis, .07 and .18; Violence, .06 and .19; Staying out late at night, .06 and -.03; Rude, .06 and .13; Victim of sex abuse, .06 (girls); Conduct prognosis bad, .05 and .18; Clean, .04 and .06; Defiant, .03 and .09; Former convulsions, .03 and .07; Vicious home conditions, .03 and -.05; Grouped: lack of interest in school, etc., .02 and .02; Exclusion from school, .02 and .12; Temper display, .02 and -.00; Slovenly, .02 and .05; Inattentive in school, .02 and -.02; Destructive, .02 and .08; Contrary, .02 and .09; Swearing (general), .01 (boys); Preference for younger children, .01 and -.08; Excuse-forming, .01 and .03; Bashful, .00 and .16; Fighting, .00 and -.04; Stubborn, -.00 and .16; Grouped: swearing, etc., -.01 and .10; Grouped: dull, slow, etc., -.01 and -.16; Underweight, -.01 and .05; Threatening violence, -.01 (boys); Lack of interest in school, -.01 and .05; Fantastical lying, -.01 and .19; Inefficient in work, play, etc., -.02 and .10; Lazy, -.02 and -.02; Teasing other children, -.02 (boys); Absent-minded, -.02 and .05; Discord between parents, -.03 and .04; Popular, -.03 and .15; Sulky, -.03 and .08; Irresponsible, -.04 and .13; Vocational guidance, -.04 and .02; Leader, -.05 and -.01; Bad companions, -.05 and .03; Smoking, -.06 (boys); Sullen, -.06 and .08; Loitering, -.08 and -.02; Lying, -.08 and .04; Truancy from home, -.08 and .05; Repressed, -.08 and -.18; Poor work in school, -.08 and -.01; Stealing, -.09 and .03; Incurable, -.10 and .02; Gang, -.10 (boys); Truancy from school, -.11 and -.03; Follower, -.12 and -.08; Attractive manner, -.12 and -.11; Irregular attendance at school, -.12 and .02; Oversuggestible, -.13 and .19; Distractible, -.14 and .12; Disturbing influence in school, -.16 and -.04; Slow, dull, -.19 and -.12

of personality, changeable moods, and sensitiveness in general.

Four additional behavior problems showed substantial correlations of .30-.32 among girls but low positive coefficients of less than .20 among boys: egocentricity, selfishness, boastful or "show-off"

manner, and irregular sleep habits.

Queer behavior (among both sexes) and stuttering (calculated for boys only) showed correlations in the .20's. Seven personality problems showed moderate correlations in the .20's among boys but lesser though positive correlations below .20 among girls: "spoiled child," inferiority feelings, seclusiveness, apprehensiveness, irritable temperament, restlessness in sleep, and overinterest in sex matters. The following nine behavior and other notations showed moderate correlations in the .20's among girls but low or negligible ones among boys: temper tantrums, crying spells, unpopularity, leading others into bad conduct, bossy manner, restlessness, finicky food habits, masturbation, and neurological defect (unspecified).

Several negative correlations of significant size were found. Brother in penal detention among our girls showed the substantial negative association of  $-.34 \pm .07$  with psychoneurotic trends, the corresponding coefficient for our boys of  $-.22 \pm .06$  also being of significant size. Feeble-minded sibling showed similar negative association though of lesser size, the coefficient for girls being  $-.23 \pm .07$  and for boys  $-.16$ . Among our cases, then, children who have a delinquent brother or a mentally defective sibling appeared to be less psychoneurotic than were the children with more normal siblings. Question of hypophrenia and retardation in school showed similarly negative tetrachoric correlations ranging from  $-.21$  to  $-.29$  among both sexes. With intelligence as measured by intelligence quotient (IQ), it will be recalled from our Table 10 (p. 130) that there were slight positive bi-serial correlations of  $.20 \pm .03$  and  $.16$  among boys and girls respectively. Lues yielded negative coefficients of  $-.26 \pm .07$  and  $-.19$  for boys and girls respectively. Speech defect (other than stuttering) showed a moderate negative correlation of  $-.21 \pm .07$  among our girls but practically zero correlation among boys.

Among girls the tetrachoric correlation of lack of initiative with psychoneurotic trends was not calculable because there were no instances in which these two notations were made in the case of the same girl. Among boys the correlation was  $.19$ .

Among our six sex notations there were only two instances of statistically significant correlations with psychoneurotic trends: among boys the correlation for overinterest in sex matters

was  $.21 \pm .07$ , the corresponding coefficient for girls being quite negligible; and among girls the correlation for masturbation was  $.23 \pm .06$ , the corresponding coefficient for boys being only  $.15$ . Sex delinquency (coitus) among boys showed the low positive correlation of  $.17$ , while the girls' coefficient was quite negligible. Overinterest in opposite sex, which was calculated for girls only, yielded the low correlation of  $.19$ . Victim of sex abuse and sex misbehavior denied entirely yielded practically zero correlations.

Neurological defect among girls showed the moderate correlation of  $.23 \pm .07$ . Stuttering among boys showed the moderate correlation of  $.29 \pm .07$ , the corresponding coefficient for girls being omitted because of paucity of cases. Lues among boys and speech defect (other than stuttering) among girls showed moderate negative correlations in the  $.20$ 's. Enuresis, underweight condition, and question of encephalitis showed negligible correlations below  $.20$  among both sexes.

Discord between parents and vicious home conditions among both sexes and immoral home conditions among girls showed practically zero correlations with psychoneurotic trends. Among boys the correlation for immoral home conditions was slightly positive,  $.19$ . Brother in penal detention, however, showed moderate to substantial negative coefficients, as noted above.

Question of "spoiled" or overindulged child was noted in 250 (or 11.8 per cent) of our boys and in 112 (or 9.5 per cent) of our girls. It was correlated to a substantial but not high extent with the personality-total and the conduct-total but negligibly with police arrest.

Its highest correlation (Table 24) was among girls,  $.42 \pm .06$ , with violence, the correlation among boys being only  $.16$ . The next highest correlation was for boastful or "show-off" manner,  $.32 \pm .04$  and  $.38 \pm .06$  among boys and girls respectively. Fantastical lying yielded correlations of  $.31 \pm .05$  and  $.30 \pm .06$  for boys and girls respectively. Among girls three behavior problems yielded substantial correlations ranging from  $.30$  to  $.38$ , while among boys the coefficients were of moderate size in the  $.20$ 's: "nervousness" or restlessness (undifferentiated), bossy manner, and temper tantrums. Six additional behavior traits also showed substantial correlations in the  $.30$ 's for girls but low positive

Other Correlations (Positive to Negative)

Restless, .19 and .19; Lying, .18 and .17; Unhappy, .18 and -.00; In-corrigible, .17 and .19; Sulky, .17 and .10; Grouped: lack of interest in school, etc., .17 and .19; Grouped: depressed, etc., .17 and .10; Lazy, .16 and .11; Bashful, .16 and -.05; Queer, .16 and .10; Unpopular, .16 and .17; Wor-ry over specific fact, .16 and .19; Gang, .15 (boys); Threatening violence, .15 (boys); Masturbation, .15 and .01; Lack of initiative, .15 and .00; Poor work in school, .15 and .10; Excuse-forming, .19 and -.01; Bad companions, .13 and .14; Enuresis, .13 and .10; Stealing, .13 and .05; Restless in sleep, .13 and .17; Grouped: swearing, etc., .13 and .02; Nail-biting, .12 and .13; Irregu-lar attendance at school, .12 and .01; Depressed, .12 and .14; Discord between parents, .12 and .02; Complaining of bad treatment by other children, .12 (boys); Sex denied entirely, .12 and .17; Lack of interest in school, .11 and .13; Slowly, .11 and -.03; Staying out late at night, .11 and .19; Leader, .11 and .12; Quarrelsome, .10 and .12; Apprehensive, .10 and .09; Oversuggest-ible, .10 and .03; Truancy from school, .09 and .16; Headaches, .09 and .04; Fighting, .08 and .18; Smoking, .08 (boys); Swearing (general), .08 (boys); Listless, .08 and -.01; Truancy from home, .07 and .07; Conduct prognosis bad, .07 and .12; Temper display, .06 and .09; Repressed, .06 and .04; Preference for younger children, .06 and .09; Clean, .06 and .06; Vocational guidance, .06 and .13; Former convulsions, .05 and .08; Stuttering, .04 (boys); Underweight, .04 and .14; Exclusion from school, .03 and .09; Overinterest in sex matters, .02 and .17; Overinterest in opposite sex, .02 (girls); Follower, .01 and .01; Victim of sex abuse, .01 (girls); Question of hypophrenia, -.01 and -.08; Speech defect, -.03 and .06; Sex delinquency (coitus), -.06 and -.08; Vicious home con-ditions, -.07 and -.19; Slow, dull, -.08 and .08; Immoral home conditions, -.08 and -.18

correlations below .20 for the boys: selfishness, defiant attitude, sullenness, question of encephalitis, question of change of personality, and emotional instability.

The following ten notations showed moderate correlations in the .20's for both boys and girls: sensitiveness or worrisomeness (undifferentiated), irritable temperament, irregular sleep habits, distractibility, disobedience or incorrigibility (including stubbornness, contrariness, and defiant attitude [undifferentiated]), rudeness, disturbing influence in school, finicky food habits, attractive manner, and (calculated for boys only) teasing other children. Ten traits showed moderate correlations with "spoiled child" in the .20's for the boys but low positive correlations below .20 for the girls: psychoneurotic trends, inferiority feelings, sensitiveness over specific fact, seclusiveness, hatred or jealousy of sibling, object of teasing by other children, inefficiency in work, play, etc., destructiveness, loitering or loafing, and popularity. A group of eleven notations showed moderate correlations ranging from .27 down to .21 among the girls but negligible or low positive correlations below .20 for the boys: mental conflict, daydreaming, absent-mindedness, inattentiveness in school, changeable moods, crying spells, irresponsibility, leading others into bad conduct, refusal to attend school, fighting or quarrelsomeness (undifferentiated), and neurological defect (unspecified).

Several negative correlations of significant size were found, the highest being for girls,  $-.45 \pm .05$  for feeble-minded sibling, while the corresponding boys' correlation was only  $-.17$ . The next highest negative correlation, also among the girls, was  $-.36 \pm .05$  for brother in penal detention, the corresponding correlation for boys being  $-.11$ . (These correlations are indeed curious and again raise the question of the validity of much of our case-record data. One can see no reason a priori why families with a mentally deficient child or a delinquent son appear to be more free of "spoiled children" than the remainder of the families included in our data or why any tendency toward this immunity seems to be so much greater in the case of daughters than in the case of sons.) Girls showed similar negative correlations of  $-.24 \pm .04$  and  $-.29 \pm .04$  with retardation in school and with dull, slow, listless, or unambitious manner (undifferentiated) respectively,

the corresponding coefficients for boys being of lesser size. Another curious negative correlation is that for lues among boys,  $-.27 \pm .05$ , the corresponding coefficient for girls being quite negligible,  $-.05$ .

Among the six sex notations all correlations with "spoiled child" were low but positive, ranging from .01 to .17, the highest correlations, oddly enough, being for sex misbehavior denied entirely.

Underweight condition, enuresis, and speech defect (other than stuttering) also showed low or negligible correlations.

Among our four undesirable home conditions—discord between parents, vicious and immoral home conditions, and brother in penal detention—all correlations were low or negligible, except for brother in penal detention among girls with its substantial negative coefficient of  $-.36 \pm .05$ .

CHAPTER XIX

COMPLAINING OF BAD TREATMENT AND OBJECT OF  
TEASING (BY OTHER CHILDREN)

Complaining of bad treatment by other children (which was calculated for boys only because of the paucity of girls' cases) was correlated more substantially with object of teasing by other children than with any other of the 111 behavior traits considered in this study, the tetrachoric  $r$  being  $.43 \pm .04$  (Table 25). Their correlations with other traits showed many similarities. Complaining of bad treatment by other children appears to be of substantial

## Other Correlations (Positive to Negative)

Lack of interest in school, .19; Refusal to attend school, .19; Truancy from school, .19; Masturbation, .19; Hatred or jealousy of sibling, .19; Grouped: lack of interest in school, etc., .19; Grouped: depressed, etc., .19; Boastful, "show-off," .18; Teasing other children, .18; Staying out late at night, .18; Distractible, .18; Sensitive over specific fact, .18; Worry over specific fact, .18; Unhappy, .18; Inattentive in school, .18; Inefficient in work, play, etc., .17; Stealing, .17; Grouped: temper, etc., .17; Swearing (general), .16; Daydreaming, .16; Sensitive (general), .16; Bossy, .15; Sulky, .15; Excuse-forming, .15; Egocentric, .15; Vicious home conditions, .15; Apprehensive, .14; Conduct prognosis bad, .14; Poor work in school, .14; Grouped: egocentric, etc., .14; Lazy, .13; Nail-biting, .13; Stubborn, .13; Irritable, .13; Former convulsions, .13; Defiant, .12; Leading others into bad conduct, .12; Overinterest in sex matters, .12; Spoiled child, .12; Clean, .12; Irresponsible, .11; Question of hypochondria, .11; Stuttering, .11; Bad companions, .10; Loitering, .10; Restless in sleep, .10; Irregular attendance at school, .10; Sullen, .09; Temper display, .09; Depressed, .09; Psychoneurotic, .09; Oversuggestible, .08; Mental conflict, .08; Attractive manner; Restless, .07; Speech defect, .07; Brother in penal detention, .07; Follower, .07; Discord between parents, .07; Smoking, .07; Sex denied entirely, .06; Selfish, .05; Slow, dull, .04; Leader, .04; Neurological defect, .04; Finicky food habits, .03; Enuresis, .03; Gang, .01; Listless, .01; Preference for younger children, .01; Grouped: dull, slow, etc., .01; Retardation in school, .00; Repressed, -.01; Absent-minded, -.02; Sex delinquency (coitus), -.03; Bashful, -.03; Lack of initiative, -.03; Lues, -.05; Underweight, -.07; Vocational guidance, -.07; Immoral home conditions, -.07; Feeble-minded sibling, -.11; Popular, -.14

or at least moderate importance as a clinical notation, as may be inferred from its correlations with personality-total, conduct-total, and police arrest, with correlation coefficients ranging from .36 down to .22. It was noted among 121 of our 2,113 White

boys, i.e., in 5.7 per cent of cases.

Another correlation of substantial size was with unpopularity (.38 ± .06). There were about thirty notations showing correlations ranging from .29 down to .20, the more meaningful among the personality problems being for question of change of personality, seclusiveness, changeable moods, queer behavior, inferiority feelings, emotional instability, and "nervousness" and among conduct problems such aggressive behavior difficulties as disturbing influence in school, disobedience (together with incurability and contrariness), fighting and quarrelsomeness, violence and destructiveness, temper tantrums, swearing or bad language (undifferentiated), truancy from home, and lying.

Among the four sex notations studied among the boys, mas-turbation showed a low positive tetrachoric  $r$  of .19, the other coefficients being of negligible size.

Among the seven physical or psychophysical notations, question of encephalitis showed the moderate correlation of .23 ± .07, all other correlations in this field being of negligible size.

The tetrachoric correlation of complaining of bad treatment by other children with teasing other children was .18 (calculated for boys only). This suggests a trend toward a compensatory relation between the two, i.e., boys who tease others may tend to complain that others mistreat them.

Object of teasing or of unpleasant nicknaming by other children was noted among 312 instances, or 14.8 per cent, of our boys and among 91 instances, or 7.7 per cent, of the girls and was one of the most frequent of personality problems in our data. It was especially characteristic of younger children, as one may suppose.<sup>1</sup> It was particularly characteristic of less intelligent children, especially among those of adolescent age.<sup>2</sup> It was moderately correlated with the personality-total among both sexes and among girls also with the conduct-total, with bi-serial coefficients ranging from .27 to .30. There was almost no correlation with police arrest.

---

<sup>1</sup>I, 151, Fig. 27, and 205, Fig. 48, and this volume, Table 9 (p. 128).

<sup>2</sup>I, 151, Fig. 27, and this volume, Table 10 (p. 130).

Among boys its highest correlation was with complaining of bad treatment by other children, .42 ± .04 (Table 26). Among girls: the highest correlations were with disturbing influence in school

## Other Correlations (Positive to Negative)

Sensitive (general), .19 and .18; Poor work in school, .19 and .14; Hatred or jealousy of sibling, .18 and .13; Question of hypophrenia, .17 and .18; Stuttering, .16 (boys); Seclusive, .16 and .01; Threatening violence, .16 (boys); Destructive, .16 and .06; Boastful, "show-off," .16 and .13; Grouped: temper, etc., .14 and .18; Lack of initiative, .14 and -.11; Apprehensive, .14 and .14; Swearing (general), .14 (boys); Inefficient in work, play, etc., .13 and .08; Grouped: dull, slow, etc., .13 and .05; Grouped: depressed, etc., .12 and .13; Lazy, .12 and .07; Disobedient, .11 and .17; Irresponsible, .11 and .15; Refusal to attend school, .11 and -.01; Stubborn, .11 and .12; Slow, dull, .11 and .06; Psychoneurotic, .11 and .05; Irregular sleep habits, .11 and .14; Restless in sleep, .11 and .17; Unhappy, .10 and .12; Conduct prognosis bad, .10 and .08; Oversuggestible, .10 and -.04; Depressed, .10 and .14; Absent-minded, .10 and -.01; Quarrelsome, .10 and .13; Lying, .09 and .18; Teasing other children, .09 (boys); Slovenly, .09 and .09; Temper tantrums, .09 and .05; Overinterest in opposite sex, .09 (girls); Enuresis, .08 and .14; Leading others into bad conduct, .07 and .08; Nail-biting, .07 and .19; Staying out late at night, .07 and .14; Excuse-forming, .07 and .16; Irritable, .06 and .15; Bashful, .06 and .07; Loitering, .06 and -.04; Finicky food habits, .05 and .14; Rude, .05 and .10; Listless, .05 and -.01; Egocentric, .04 and -.07; Truancy from school, .03 and .17; Overinterest in sex matters, .03 and .03; Vicious home conditions, .03 and -.07; Grouped: egocentric, etc., .03 and -.10; Sex denied entirely, .02 and -.13; Underweight, .02 and .07; Stealing, .02 and .19; Bad companions, .02 and .14; Retardation in school, .01 and .05; Irregular attendance at school, .01 and .06; Smoking, -.00 (boys); Follower, -.00 and .13; Attractive manner, -.00 and .08; Sex delinquency (coitus), -.01 and -.08; Selfish, -.02 and .06; Clean, -.02 and -.09; Truancy from home, -.03 and .15; Discord between parents, -.07 and -.06; Feeble-minded sibling, -.07 and .00; Brother in penal detention, -.07 and .07; Popular, -.07 and .10; Victim of sex abuse, -.07 (girls); Gang, -.08 (boys); Leader, -.09 and -.19

(.45 ± .06), fighting (.43 ± .03), and sensitiveness over some specific fact (.41 ± .05), the corresponding coefficients for boys being .18, .20 ± .03, and .30 ± .03 respectively.

Among both sexes three personality difficulties yielded substantial tetrachoric correlations ranging from .30 to .38: inferiority feelings, queer behavior, and unpopularity. Among girls three notations yielded substantial correlations in the .30's with corresponding moderate coefficients for boys in the .20's: sensitiveness or worrisomeness (undifferentiated), violence, and question of encephalitis. The following five notations also showed substantial correlations in the .30's for girls but low coefficients ranging from .10 to .18 among boys: exclusion from school, bossy manner, fighting or quarrelsomeness (undifferentiated), "nervousness" or restlessness (undifferentiated), and distractibility.

Two personality problems showed moderate correlations in the .20's for both boys and girls—question of change of personality and preference for younger children as playmates. The following seven notations showed moderate correlations in the .20's for boys but low positive correlations below .20 for girls: masturbation, emotional instability, daydreaming, "nervousness," "spoiled child," temper display other than "tantrums," and headaches. The following sixteen case notations showed moderate coefficients among the girls, ranging from .29 down to .20, but low or negligible coefficients below .20 among boys: inattentiveness in school, lack of interest in school studies or employment, restlessness, crying spells, mental conflict, repressed manner, changeable moods, swearing or bad language (undifferentiated), disobedience (including incorrigibility, defiant manner, and contrariness), sulkiness, sullenness, fantastical lying, speech defect (other than stuttering), neurological defect (unspecified), former convulsions, and lues.

Only two case notations showed significant negative correlations, both among girls: immoral (other than vicious) home conditions,  $-.23 \pm .06$ , and vocational or educational guidance,  $-.22 \pm .05$ , the corresponding coefficients among boys being also negative or of small size.

Among the six sex notations the only significant correlation with object of teasing by other children was masturbation among boys,  $.29 \pm .03$ , the other correlations being quite negligible.

Among physical defects, substantial correlations were found for question or diagnosis of encephalitis (present or former), the coefficients for girls and boys respectively being  $.26 \pm .05$  and  $.30 \pm .08$ , for neurological defect (unspecified) with the respective coefficients of  $.19$  and  $.27 \pm .06$ , for lues with respective coefficients of  $-.06$  and  $.22 \pm .07$ , and for speech defect (other than stuttering) with respective coefficients of  $.15$  and  $.21 \pm .06$ . Low or negligible correlations were found for underweight condition, enuresis (present or former), and, oddly enough, for stuttering (which was calculated for boys only).

Among unfavorable home conditions there were the interesting negative coefficients of  $-.16$  and  $-.23 \pm .06$  with immoral home conditions for boys and girls respectively, but for vicious home conditions, brother in penal detention, and discord between parents the correlations were negligible.

Our boys who are themselves object of teasing by other children apparently do not tend to "compensate" therefor by teasing other children, as we may infer from the quite negligible tetrachoric correlation of  $-.06$  between these notations. (This correlation unfortunately could not be calculated for girls because of the paucity of cases.)

CHAPTER XX

UNPOPULARITY AND POPULARITY

Unpopularity among schoolmates or playmates, or marked lack of popularity appears to be among the more meaningful behavior problems from a clinical standpoint, as indicated by its very substantial or high bi-serial correlations ranging from .39 to .64 with both personality-total and conduct-total. It is curious, however, that in view of its negligible tetrachoric correlations with police arrest it appears to be of no significance as far as overt "juvenile delinquency" is concerned. It was noted among 110 of our 2,113 White boys (5.2 per cent) and among 54 of our 1,181 White girls (4.6 per cent).

Its highest correlations (Table 27) were among girls, the coefficients ranging from .54 down to .49 for the five conduct difficulties, bossy manner, lying, boastful or "show-off" manner, and

## Other Correlations (Positive to Negative)

Overinterest in sex matters, .18 and .18; Masturbation, .17 and .18; Spoiled child, .16 and .17; Bashful, .16 and -.08; Temper display, .16 and .10; Absent-minded, .15 and -.09; Sensitive (general), .15 and -.01; Refusal to attend school, .14 and -.00; Slovenly, .13 and .15; Truancy from home, .13 and .16; Stuttering, .13 (boys); Discord between parents, .13 and -.00; Grouped: sensitive or worrisome, etc., .12 and .17; Clean, .12 and -.08; Truancy from school, .12 and .17; Neurological defect, .11 and .15; Underweight, .08 and .13; Unhappy, .06 and .09; Former convulsions, .06 and .04; Bad companions, .04 and .10; Sex denied entirely, .03 and .08; Question of hypochondria, .02 and .11; Finicky food habits, .02 and .11; Follower, .01 and -.11; Headaches, .01 and .01; Speech defect, .01 and .13; Vicious home conditions, .01 and .06; Hatred or jealousy of sibling, -.01 and .16; Brother in penal detention, -.04 and -.04; Irregular attendance at school, -.05 and .07; Slow, dull, -.05 and -.02; Victim of sex abuse, -.05 (girls); Vocational guidance, -.06 and -.17; Grouped: dull, slow, etc., -.08 and -.02; Sex delinquency (coitus), -.09 and .18; Listless, -.09 and .17; Repressed, -.10 and .09; Retardation in school, -.10 and -.05; Gang, -.11 (boys); Immoral home conditions, -.16 and -.11

disturbing influence in school. Swearing or bad language (undifferentiated) also yielded substantial coefficients of .42 ± .07 for girls and .31 ± .05 for boys. Three other behavior traits

yielded substantial coefficients in the .40's for the girls but moderate correlations in the .20's for the boys: violence, leading others into bad conduct, and question of change of personality.

Five behavior traits yielded substantial correlations in the .30's for both boys and girls: fantastical lying, egocentricity or selfishness (undifferentiated), inefficiency in work, play, etc., disobedience or incorrigibility (including stubbornness, contrariness, and defiant attitude, undifferentiated), and object of teasing by other children. Two notations which were calculated for boys only—teasing other children and complaining of bad treatment by other children—also yielded substantial coefficients in the .30's. Fighting yielded a substantial correlation of  $.39 \pm .04$  among boys and a moderate correlation of  $.28 \pm .04$  among girls. The following five behavior traits among girls yielded substantial correlations in the .30's but among boys moderate coefficients in the .20's: queer behavior, rudeness, "nervousness" or restlessness (undifferentiated), crying spells, and temper tantrums. The following seven notations among girls yielded substantial correlations in the .30's but low positive correlations below .20 for the boys: incorrigibility, stealing, exclusion from school, restlessness, restlessness in sleep, changeable moods, and emotional instability. Overinterest in the opposite sex, for which only the girls' correlation was computed, yielded a substantial coefficient of  $.34 \pm .06$ .

The following nine behavior traits showed moderate correlations in the .20's for both sexes: inferiority feelings, depressed spells, daydreaming, inattentiveness in school, distractibility, excuse-forming attitude, laziness, selfishness, and staying out late at night. Three conduct difficulties for which only the boys' coefficients were computed—threatening violence, swearing (general), and smoking—also showed moderate correlations in the .20's.

The following eleven conduct and personality difficulties showed moderate correlations in the .20's among boys but low positive correlations below .20 among the girls: contrariness, destructiveness, "nervousness," irritable temperament, irregular sleep habits, loitering or loafing, sullenness, lack of interest in school work, irresponsibility, seclusiveness, and oversuggestibility. The following fifteen notations among girls showed mod-

erate correlations in the .20's, but low coefficients below .20 for the boys: defiant attitude, stubbornness, sulkiness, psycho-neurotic trends, mental conflict, worry over specific fact, sensitiveness over some specific fact, apprehensiveness, preference for younger children as playmates, poor work in school, enuresis, nail-biting, staff diagnosis of unfavorable conduct prognosis, "leader," and question or diagnosis of encephalitis.

Two negative coefficients of significant magnitude were found among the girls' correlations: attractive manner,  $-.23 \pm .06$ , and lack of initiative,  $-.22 \pm .09$ , the corresponding boys' correlations being negligible.

Among the six sex notations there was only one coefficient of significant size, overinterest in opposite sex (calculated for girls only),  $.34 \pm .06$ .

Among the seven physical or psychophysical notations there were among the girls two correlations of moderate size: enuresis,  $.22 \pm .06$ , and question or diagnosis of encephalitis,  $.22 \pm .10$ . The boys' coefficients for these two notations and all coefficients for underweight condition, neurological defect (unspecified), head-aches, speech defect, and (calculated for boys only) stuttering were positive but of negligible size, ranging from .01 to .15.

For the four undesirable home or familial conditions the coefficients were of negligible size.

In order that comparisons could be made with the usual "behavior difficulties," the notation popularity among schoolmates or playmates or "patient is well liked" is included as one of the frequently appearing behavior traits not considered as undesirable. It was noted among 138 of our boys and 76 of our girls. Its correlations with our three criteria of "seriousness" or "ominousness" were all of nonsignificant size, ranging from .03 to .13 (Table 28). It yielded only a few correlations of significant size. Its highest correlations among both sexes were with the "desirable" traits, attractive manner and "leader," the coefficients ranging from .32 to .40. Another substantial correlation was the negative one of  $-.39 \pm .04$  with daydreaming among boys, the girls' coefficient being negligible, .06. Apparently children who are popular, especially boys, do not need to resort to daydreaming. (With unpopularity the correlations with daydreaming were positive,

Sex delinquency (coitus), .18 and -.01; Grouped: sensitive or worrisome, etc., .18 and .06; Defiant, .17 and .12; Smoking, .17 (boys); Staying out late at night, .17 and .04; Boastful, "show-off," .16 and .18; Refusal to attend school, .16 and .18; Sulky, .16 and .17; Irresponsible, .15 and .02; Masturbation, .13 and .01; Irregular sleep habits, .13 and .15; Question of encephalitis, .13 and .14; Vocational guidance, .13 and .06; Teasing other children, .12 (boys); Overinterest in sex matters, .12 and .04; Restless in sleep, .12 and .03; Sensitive over specific fact, .12 and .00; Fighting, .11 and .12; Stealing, .11 and -.01; Destructive, .09 and -.02; Incurable, .09 and .05; Slovenly, .09 and -.01; Lack of initiative, .09 and -.07; Exclusion from school, .09 and .03; Truancy from home, .09 and .03; Stuttering, .09 (boys); Inattentive in school, .08 and .05; Inefficient in work, play, etc., .08 and -.00; Lying, .08 and .02; Slow, dull, .08 and -.13; Grouped: disobedient, etc., .08 and .07;

TABLE 28—Continued

Bad companions, .07 and .10; Disobedient, .07 and .05; Gang, .07 (boys); Temper tantrums, .07 and .16; Stubborn, .07 and .02; Absent-minded, .07 and -.05; Changeable moods, .07 and .03; Irritable, .07 and .13; Question of change of personality, .06 and .19; Listless, .06 and -.10; Grouped: temper, etc., .06 and .12; Grouped: lack of interest in school, etc., .06 and .03; Lazy, .05 and -.02; Sullen, .05 and .03; Truancy from school, .05 and -.12; Hatred or jealousy of sibling, .05 and .08; Bashful, .05 and .06; Crying spells, .05 and .09; Restless, .05 and .03; Repressed, .05 and -.08; Nail-biting, .04 and -.07; Rude, .04 and .04; Sex denied entirely, .04 and .13; Grouped: "nervous," etc., .04 and .07; Grouped: fighting, etc., .04 and .03; Fantastical lying, .03 and .01; Swearing (general), .03 (boys); Violence, .03 and .11; Disturbing influence in school, .02 and .12; Enuresis, .02 and -.03; "Nervous," .02 and .06; Poor work in school, .02 and -.01; Quarrelsomeness, .01 and -.09; Unhappy, .01 and .05; Apprehensive, .00 and .12; Excuse-forming, .00 and .14; Oversuggestible, .00 and -.01; Neurological defect, .00 and .02; Headaches, -.00 and .11; Speech defect, -.00 and -.03; Discord between parents, -.00 and -.10; Grouped: swearing, etc., -.00 and .01; Lack of interest in school, -.01 and -.04; Immoral home conditions, -.01 and -.19; Distractable, -.02 and .18; Grouped: depressed, etc., -.02 and -.05; Leading others into bad conduct, -.03 and .17; Depressed, -.03 and -.13; Psychoneurotic, -.03 and .15; Emotional instability, -.03 and .11; Overinterest in opposite sex, -.03 (girls); Temper display, -.04 and -.06; Inferiority feelings, -.04 and -.06; Preference for younger children, -.04 and -.06; Grouped: dull, slow, etc., -.04 and -.09; Selfish, -.05 and .07; Ego-centric, -.06 and .19; Grouped: egocentric, etc., -.06 and .15; Contrary, -.07 and .11; Threatening violence, -.07 (boys); Object of teasing, -.07 and .10; Underweight, -.07 and -.10; Question of hypochondria, -.08 and -.14; Follower, -.08 and .10; Victim of sex abuse, -.08 (girls); Queer, -.11 and .04; Former convulsions, -.13 and .04; Bossy, -.14 and .12; Complaining of bad treatment by other children, -.14 (boys); Irregular attendance at school, -.14 and -.07; Brother in penal detention, -.14 and -.19; Retardation in school, -.18 and -.12; Seclusive, -.19 and -.14

.26 ± .05 and .26 ± .07 for boys and girls respectively.)

Popularity showed some statistically significant positive correlations in the .20's with three undesirable behavior traits: finicky food habits and "spoiled child" among boys, and sensitivity in general among girls, the corresponding coefficients for the other sex being low but positive. With the notation clean, neat habits or appearance the correlations were .17 and .25 ± .06 for boys and girls respectively.

Additional meaningful correlations of negative sign for boys and girls, respectively, were for mental conflict, -.24 ± .06 and .01, for worry over specific fact, .05 and -.20 ± .09, and for staff notation of unfavorable conduct prognosis, -.09 and -.27 ± .08.

Among the six sex notations the correlations with popularity were of negligible size, unless one considers that the positive

correlation of .18 for sex delinquency (coitus) among boys is meaningful. Among the seven physical or psychophysical notations all correlations were negligible. Among the four undesirable home or familial notations (discord between parents, vicious and immoral home conditions, and brother in penal detention) the only significant coefficient was with vicious home conditions among girls,  $-.29 \pm .07$ .

A comparison of the corresponding coefficients in Tables 27 and 28 for the presumably antithetical notations unpopularity and popularity brings to light the curious statistical phenomenon which has been previously mentioned,<sup>1</sup> i. e., the fact that many of the corresponding correlations for such antithetical pairs of traits as unpopularity-popularity, slovenliness-cleanliness, and "leader"-"follower" were not of opposite sign and of similar magnitude, as would be supposed if strictly objectively measurable traits were being used but were often of the same sign (though of different magnitude). Among the 116 pairs of corresponding coefficients for the boys in Table 27 (unpopularity) and Table 28 (popularity) there were 80 of like sign and only 36 of unlike sign. Among 113 pairs of girls' coefficients there were 77 of like sign and only 36 of unlike sign. The intercolumnar correlations (Pearson's product-moment) were  $-.08 \pm .06$  for the boys and  $.14 \pm .06$  for the girls. Now, if these two notations, unpopularity and popularity, were truly antithetical in meaning and could be considered as opposite ends of the same scale, just as "long" and "short" are the opposite ends on a scale of stature, and if the correlations between the putative trait unpopularity-popularity with other traits are based upon rectilinearity of regression, we should expect the corresponding correlations in Tables 27 and 28 to be of unlike sign and of substantially the same magnitude, and intercolumnar correlations based upon these coefficients should approach a negative unity.

In our previous discussion of this phenomenon of inconsistency between the correlation of coefficients of presumably antagonistic traits two possible theories were suggested—one a possible non-rectilinearity of specific notations on the trait unpopularity

<sup>1</sup>See I, 134-35 and 249-50, and this volume, p. 45.

ularity-popularity and the other that the traits unpopularity and popularity may not be truly opposite poles of a single underlying trait. It may be that the true "opposite" of unpopularity is "indifference." A third possibility is that this lack of negativity in correlation described in the preceding paragraph may be due to the existence of unmeasured prejudicial factors in the data as discussed in chapter iv.

## CHAPTER XXI

### DAYDREAMING AND ABSENT-MINDEDNESS

Daydreaming and absent-mindedness do not appear to be fundamentally similar traits in spite of their apparent, superficial resemblance. Their intercorrelations for boys and girls respectively were only  $.29 \pm .05$  and  $.33 \pm .07$ . Their correlations with several other traits or notations were higher than with each other.

Daydreaming or fantasying was of substantial but not serious importance clinically, as may be inferred from its bi serial correlations with the personality- and the conduct-total, which range from  $.27$  to  $.49$  (Table 29). With police arrest ("juvenile delinquency") its relations were non-significant. It was noted among 195 of our 2,113 White boys (9.2 per cent) and among 94 of our 1,181 White girls (8.0 per cent).

Daydreaming yielded its largest correlations (tetrachoric  $r$ ) among girls,  $.42 \pm .06$  with inefficiency in work, play, etc., and  $.42 \pm .06$  for boastful or "show-off" manner, the corresponding coefficients for boys being  $.26 \pm .05$  and  $.18$  respectively. Other substantial correlations in the  $.30$ 's for both boys and girls were for depressed spells, unhappy appearance or manner, inferiority feelings, queer behavior, and fantastical lying. Among boys mas-turbation yielded a correlation of  $.37 \pm .03$  with a corresponding correlation among girls of  $.25 \pm .05$ . Hatred or jealousy of sibling among boys showed a correlation of  $.30 \pm .05$ , but its coefficient among girls was negligible,  $.07$ . Among girls the following five personality difficulties yielded substantial correlations in the  $.30$ 's with moderate coefficients in the  $.20$ 's for boys: sensitiveness or worrisomeness (undifferentiated) and sensitiveness over specific fact, seclusiveness, changeable moods, and absent-mindedness. Another seven behavior problems also showed substantial correlations in the  $.30$ 's among girls but negligible coefficients ranging from  $.18$  down to  $-.00$  among boys: violence, rudeness, defiant attitude, disturbing influence in school, emotional

## Other Correlations (Positive to Negative)

Lack of interest in school, .19 and .19; Lazy, .19 and .09; Grouped: dull, slow, etc., .18 and .14; Poor work in school, .18 and .06; Preference for younger children, .18 and .05; Nail-biting, .17 and .08; Teasing other children, .17 (boys); Refusal to attend school, .16 and .12; Complaining of bad treatment by other children, .16 (boys); Neurological defect, .15 and .11; Bashful, .14 and .16; Overinterest in opposite sex, .14 (girls); Vicious home conditions, .13 and .02; Bossy, .13 and .16; Selfish, .12 and .09; Staying out late at night, .12 and .18; Psychoneurotic, .12 and .13; Immoral home conditions, .11 and .18; Temper tantrums, .11 and .19; Underweight, .10 and .06; Speech defect, .09 and -.14; Destructive, .09 and .11; Bad companions, .09 and .05; Victim of sex abuse, .09 (girls); Exclusion from school, .08 and .17; Apprehensive, .07 and .05; Swearing (general), .07 (boys); Sulky, .07 and .18; Smoking, .07 (boys); Loitering, .07 and -.05; Temper display, .06 and .14; Slow, dull, .06 and -.01; Conduct prognosis bad, .05 and .11; Oversuggestible, .05 and .08; Truancy from

TABLE 29—Continued

home, .04 and .15; Former convulsions, .04 and .04; Follower, .04 and -.01; Discord between parents, .03 and .16; Vocational guidance, .03 and -.04; Leading others into bad conduct, .03 and .16; Fighting, .02 and .16; Disobedient, .02 and .13; Stuttering, .01 (boys); Gang, -.05 (boys); Lues, -.05 and .11; Irregular attendance at school, -.06 and -.00; Question of hypophrenia, -.11 and -.15; Sex denied entirely, -.16 and .13

instability, mental conflict, and lying.

Nine behavior problems showed moderate correlations in the .20's for both sexes: "nervousness," restlessness in sleep, listlessness, lack of initiative or ambition, unpopularity, worry over some specific fact or episode, repressed manner, contrariness, stubbornness, and also one calculated for boys only, threatening violence. Another six notations showed moderate correlations in the .20's for boys but low coefficients ranging from -.01 to .16 among girls: irresponsibility, inattentiveness in school, distractibility, object of teasing by other children, sex delinquency (coitus), and clean habits. Among girls the following twenty-four notations showed moderate correlations in the .20's, with lesser coefficients ranging from -.02 to .19 among the boys: sensitiveness in general, incurability, quarrelsomeness, swearing or bad language (undifferentiated), excuse-forming attitude, stealing, truancy from school, temper display or temper tantrums (undifferentiated), egocentricity, irritable manner or disposition, sullenness, slovenliness, restlessness, irregular sleep habits, "spoiled child, crying spells, question of change of personality, overinterest in sex matters, enuresis, finicky food habits, headaches, question or diagnosis of encephalitis, attractive manner, and "leader."

The largest negative correlations with daydreaming were as follows: popularity among boys,  $-.39 \pm .04$ , with a corresponding coefficient for girls of .06, and brother in penal detention, with moderate or substantial negative correlations of  $-.22 \pm .05$  and  $-.32 \pm .06$  for boys and girls respectively. Retardation in school showed moderate correlations of  $-.21$  for both sexes. The notation, feeble-minded sibling, among girls showed the moderate correlation of  $-.21 \pm .04$  and a corresponding coefficient of  $-.09$  among boys.

Sex notations showed several significant correlations with daydreaming. Masturbation among boys showed the substantial coefficient of  $.37 \pm .03$  and a moderate coefficient of  $.25 \pm .05$  among

girls. Sex delinquency (coitus) among boys showed the moderate correlations of  $.22 \pm .06$ , but its correlation among girls was practically zero ( $-.01$ ). Overinterest in sex matters among girls showed the moderate correlation of  $.26 \pm .07$  and among boys the scarcely significant coefficient of  $.19$ . Sex misbehavior denied entirely showed the interesting but statistically non-significant coefficients of  $-.16$  and  $.13$  for boys and girls respectively. Overinterest in opposite sex and victim of sex abuse by older child or person, which were calculated for girls only, showed and the negligible coefficients of  $.14$  and  $.09$  respectively.

Among our physical or psychophysical notations, only two coefficients were of significant size, both among girls,  $.23 \pm .05$  for enuresis (present or former) and  $.29 \pm .08$  for question or diagnosis of encephalitis. All other coefficients in this field, including those for underweight condition, lues, neurological defect (unspecified), speech defect, and stuttering, were low or negligible in size. Brother in penal detention, as we have seen, yielded moderate or substantial negative correlations, while the other familial notations—discord between parents and vicious and immoral home conditions—showed negligible correlations.

Absent-mindedness, forgetfulness, or poor memory appear to be of relatively little importance clinically, unless possibly in the case of the boys, in which one finds the fairly substantial bi-serial correlation of  $.30 \pm .03$  with personality-total (Table 30). All other criteria of "importance or seriousness" showed low correlations falling between  $-.16$  and  $.18$ . It was noted among 134 boys, or 6.3 per cent, and among 62 girls, or 5.2 per cent.

Its highest correlation was with inefficiency in work, play, etc., with tetrachoric correlations of  $.47 \pm .05$  and  $.42 \pm .06$  for boys and girls respectively. Distractibility among boys yielded the fairly high correlation of  $.40 \pm .04$  and among girls the substantial correlation of  $.35 \pm .07$ . Queer behavior and head-aches also yielded substantial correlations in the .30's among boys and moderate correlations in the .20's among girls. Listlessness and irresponsibility also yielded substantial correlations in the .30's among boys but low coefficients below  $.20$  for girls. Among the girls four notations—daydreaming, mental conflict, "nervousness," and question or diagnosis of encephalitis—yielded

## Other Correlations (Positive to Negative)

Slovenly, .19 and -.03; Stubborn, .19 and .09; Temper display, .19 and -.09; Teasing other children, .18 (boys); Apprehensive, .18 and .05; Changeable moods, .18 and .02; Irritable, .18 and .06; Follower, .18 and .03; Loitering, .17 and -.10; Sulky, .17 and .14; Worry over specific fact, .16 and .11; Unpopular, .15 and -.09; Question of hypophrenia, .15 and .08; Grouped: disobedient, etc., .15 and .06; Inattentive in school, .13 and .17; Underweight, .13 and .08; Boastful, "show-off," .12 and .16; Refusal to attend school, .12 and .16; Masturbation, .12 and .15; Crying spells, .12 and .18; Sensitive over specific fact, .12 and .10; Speech defect, .12 and .08; Grouped: sensitive or worrisome, etc., .12 and .18; Disobedient, .11 and .05; Fantastical lying, .11 and .16; Vocational guidance, .11 and -.08; Object of teasing, .10 and -.01; Grouped: lack of interest in school, etc., .10 and .15; Destructive, .09 and .17; Swearing (general), .09 (boys); Overinterest in opposite sex, .09 (girls); Conduct prognosis bad, .09 and .11; Victim of sex abuse, .09 (girls); Finicky food habits, .08 and -.04; Nail-biting, .08 and .08; Selfish, .08 and .12; Bashful, .08 and -.03; Lues, .08 and .03; Lying, .07 and .14; Violence, .07 and .01; Stuttering, .07 (boys); Popular, .07 and -.05; Staying out late at night, .06 and -.18; Truancy from school, .06 and .03; Overinterest in sex matters, .06 and .13; Excuse-forming, .06 and -.12; Irregular attendance at school, .06 and -.00; Grouped: swearing, etc., .06 and .04; Grouped: depressed, etc., .06 and .13; Stealing, .05 and .13; Enuresis, .04 and .14; Incurable, .04 and .12; Truancy from home, .04 and .06; Unhappy, .04 and .07; Bossy, .03 and -.13; Disturbing influence in school, .03 and .08; Rude, .03 and .08; Vicious home conditions, .03 and -.13; Grouped: egocentric, etc., .03 and .10; Lack of interest in school, .02 and .08; Clean, .02 and .16; Repressed, .01 and .18; Leader, .01 and -.09; Immoral home conditions, .01 and -.07; Temper tantrums, .00 and .04; Sex denied entirely, .00 and -.18; Quarrelsome, -.01 and -.09; Egocentric, -.02 and .03; Psychoneurotic, -.02 and .05; Complaining of bad treatment by other children, -.02 (boys); Gang, -.04 (boys); Grouped: fighting, etc., -.04 and .01; Hatred or jealousy of sibling, -.04 and .19; Brother in penal detention, -.05 and -.07; Irregular habits, -.06 and -.02; Defiant, -.06 and .01; Bad companions, -.08 and -.00; Fighting, -.08 and .17; Feeble-minded sibling, -.08 and -.09; Retardation in school, -.09 and .08; Smoking, -.10 (boys); Threatening violence, -.11 (boys); Sex delinquency (coitus), -.16 and -.03

substantial correlations in the .30's and among boys moderate correlations in the .20's. Restlessness in sleep also yielded a substantial correlation of .31 + .06 among girls but a low coefficient of .13 among boys.

Four behavior notations showed moderate correlations in the .20's with absent-mindedness among both sexes: question of change of personality, poor work in school, slow or dull manner, and lack of initiative or ambition. Eight notations showed moderate correlations in the .20's for boys but low coefficients below .20 for girls: seclusiveness, laziness, restlessness, emotional instability, temper tantrums or display (including irritable temperament, undifferentiated), contrariness, neurological defect (unspecified),

and attractive manner. Nine additional notations showed moderate correlations in the .20's for girls but low positive coefficients below .20 for boys: inferiority feelings, depressed spells, "spoiled child", sensitiveness in general, preference for younger children as playmates, oversuggestibility, sullenness, exclusion from school, and former convulsions.

The only considerable negative correlation with absent-mindedness was among girls,  $-.20 \pm .05$  for discord between parents, the boys' coefficient being about zero.

Our six sex items showed only negligible relationships with absent-mindedness, the coefficients falling between  $-.18$  and  $.15$ .

Among our seven physical or psychophysical notations, question or diagnosis of encephalitis showed the suggestive correlations of  $.25 \pm .02$  and  $.31 \pm .09$  for boys and girls respectively. Neurological defect (unspecified) among boys also yielded a moderate correlation of  $.21 \pm .05$ . All other coefficients in this field were low or negligible.

Among our four home or familial notations only one was of statistically significant size, the negative coefficient of  $-.20 \pm .05$  among girls for discord between parents.

CHAPTER XXII

SECLUSIVENESS AND REPRESSED MANNER

The notations seclusiveness and repressed manner among girls indicate a somewhat similar behavior in view of their very substantial inter-correlation of  $.40 \pm .07$  (Table 31), but among boys this correlation was low,  $.16$ .

The notation seclusiveness, unresponsiveness, ("patient prefers to play alone or be by himself") appears to be of substantial importance from the standpoint of personality deviation but of almost negligible interest in the conduct sphere. It was noted among 254 of our 2,113 White boys, or 12.0 per cent, and among 106 of our 1,181 White girls, or 9.0 per cent. It was of relatively frequent occurrence among our clinic cases.

Its highest correlation was among girls,  $.48 \pm .06$  with inferiority feelings, the corresponding coefficient among boys being only moderate,  $.23 \pm .05$ . Two other notations also yielded fairly high correlations among girls,  $.41 \pm .06$  for listlessness and  $.40 \pm .07$  for repressed manner, the corresponding coefficients among boys being  $.34 \pm .04$  and  $.16$  respectively. Among boys the highest correlations were for queer behavior,  $.39 \pm .04$ , and for unhappy appearance or manner,  $.38 \pm .05$ , the corresponding correlations for girls being of moderate size,  $.25 \pm .07$  and  $.28 \pm .07$  respectively. Sensitiveness in general yielded the substantial correlations of  $.30 \pm .04$  among boys and  $.28 \pm .06$  among girls. The following five personality problems showed substantial correlations with seclusiveness in the .30's among girls and moderate correlations in the .20's among boys: daydreaming, depressed spells, worry over some specific fact, bashfulness, and dull or slow manner (including listlessness and lack of initiative, undifferentiated).

Four behavior problems showed moderate correlations in the .20's for both sexes: sensitiveness over some specific fact, mental conflict, question of change of personality, and contrariness. Ten behavior traits showed moderate correlations in the .20's for boys but low or negligible coefficients falling between  $-.13$  and  $.19$  for girls: psychoneurotic trends, apprehensiveness, "spoiled child," hatred or jealousy of sibling, inefficiency in work, play, etc., absent-mindedness, lack of initiative, selfishness, unpopularity, and (calculated for boys only) complaining of bad treatment by other children. Five behavior notations showed moderate correlations in the .20's for girls but low positive correlations below .20 for boys: laziness, sullenness, finicky food habits, "nervousness" or restlessness (undifferentiated), and irregular sleep habits.

The only negative correlations of statistically significant size were for "leader" with coefficients of  $-.19$  and  $-.20 \pm .07$

among boys and girls respectively.

Among the sex notations, physical and psychophysical notations, and home or familial conditions all coefficients, 31 in number, were too low to be of "statistical significance" within our data.

Staff notation or question of repressed or suppressed manner appeared to be of negligible significance as far as its correlations with out three criteria of "importance or seriousness" are concerned. It was noted among 138 of our boys, or 6.5 per cent, and among only 45 of our girls, or 3.8 per cent.

Its highest correlation was found among girls,  $.40 \pm .07$  with seclusiveness, the corresponding coefficient for boys being only  $.16$  (Table 32). Among girls the three personality problems,

## Other Correlations (Positive to Negative)

Masturbation, .19 and .04; Lazy, .15 and .10; Question of change of personality, .14 and .12; Sulky, .14 and .11; Lying, .13 and .05; Bashful, .13 and .00; Immoral home conditions, .13 and .17; Preference for younger children, .12 and .00; Refusal to attend school, .10 and -.08; Fantastical lying, .10 and -.08; Teasing other children, .09 (boys); Rude, .09 and .03; Stealing, .09 and .03; Overinterest in sex matters, .09 and .06; Victim of sex abuse, .08 (girls); Bad companions, .07 and -.03; Finicky food habits, .07 and .15; Enuresis, .07 and .12; Changeable moods, .07 and .03; Restless in sleep, .07 and .09; Sex denied entirely, .07 and .12; Lies, .07 and .11; Discord between parents; .06 and .16; Spoiled child, .06 and .04; Oversuggestible, .06 and -.00; Temper tantrums, .06 and .18; Stubborn, .06 and .02; Slovenly, .06 and -.01; Quarrelsome, .05 and .08; Violence, .05 and -.04; Sex delinquency (coitus), .05 and -.08; Crying spells, .05 and .15; Worry over specific fact, .05 and .18; Popular, .05 and -.08; Vicious home conditions, .04 and -.06; Neurological defect, .04 and .06; Attractive manner, .04 and .03; Lack of initiative, .04 and .13; Slow, dull, .04 and .18; Nail-biting, .04 and .06; Irresponsible, .04 and -.17; Bossy, .03 and .15; Inattentive in school, .03 and .16; Gang, .03 (boys); Stuttering, .03 (boys); Grouped: swearing, etc., .03 and .10; Grouped: lack of interest in school, etc., .02 and .17; Grouped: fighting, etc., .02 and .11; Poor work in school, .02 and .09; Overinterest in opposite sex, .02 (girls); Defiant, .01 and .04; Inefficient in work, play, etc., .01 and .11; Lack of interest in school, .01 and .12; Smoking, .01 (boys); Truancy from home, .01 and -.01; Absent-minded, .01 and .18; Irregular sleep habits, .01 and .05; "Nervous," .01 and .15; Grouped: "nervous," etc., .01 and .09; Grouped: egocentric, etc., .01 and .05; Brother in penal detention, .00 and -.15; Truancy from school, .00 and .09; Leading others into bad conduct, .00 and .12; Excuse-forming, -.00 and

TABLE 32—Continued

.09; Headaches, -.01 and .07; Complaining of bad treatment by other children, -.01 (boys); Egocentric, -.02 and .13; Vocational guidance, -.02 and .01; Irregular attendance at school, -.02 and .14; Swearing (general), -.03 (boys); Disobedient, -.03 and .04; Incurable, -.04 and -.00; Restless, -.04 and -.00; Grouped: disobedient, etc., -.04 and .04; Underweight, -.05 and .14; Former convulsions, -.06 and -.13; Threatening violence, -.06 (boys); Irritable, -.07 and .06; Distractible, -.07 and .05; Exclusion from school, -.07 and .05; Grouped: temper, etc., -.07 and .07; Psychoneurotic, -.08 and -.18; Staying out late at night, -.08 and -.19; Disturbing influence in school, -.08 and .01; Retardation in school, -.10 and -.13; Unpopular, -.10 and .09

unhappiness, depressed spells, and contrariness, yielded substantial correlations ranging from .30 to .32, while among boys the corresponding correlations ranged from .08 to .20.

Three personality notations—daydreaming, mental conflict, and sullenness—showed moderate correlations ranging from .20 to .22 among both sexes. Apprehensiveness and sensitiveness over some specific fact showed moderate correlations of .21 + .04 and .20 + .04 among boys and slightly lower correlations of .19 and .17 among girls. Eleven notations showed moderate correlations in the .20's among girls but low correlations ranging from -.02 to .18 among boys: sensitiveness in general, inferiority feelings, queer behavior, hatred or jealousy of sibling, dull or slow manner (undifferentiated), listlessness, object of teasing by other children, fighting, destructiveness, boastful or "show-off" manner, and clean habits or appearance.

With repressed manner eight case notations showed negative correlations larger than -.20. For emotional instability the coefficients were -.26 + .06 and .06 for boys and girls respectively. Among girls both notations speech defect and feeble-minded sibling yielded correlations of -.30, with negligible coefficients for boys. The following five behavior traits yielded negative coefficients among girls ranging from -.21 to -.29 with negligible coefficients among boys: temper display, selfishness, question of hypochondria, "leader," and "follower."

In three instances a tetrachoric  $r$  could not be calculated: there were no instances in which repressed children also were thought to have suffered from encephalitis or noted as given to loitering or wandering, or considered by the examining staff to manifest an unfavorable conduct prognosis.

All six sex notations showed negligible correlations with repressed manner. Among physical or psychophysical notations speech defect among girls yielded a negative correlation of  $-.30 \pm .08$ , the other coefficients being negligible. Among home or familial conditions there were no significant relationships discovered.

## CHAPTER XXIII

### QUEER BEHAVIOR AND CHANGE OF PERSONALITY

The two closely interrelated notations "queerness"—patient considered by others as mentally peculiar, very erratic, or "crazy"—etc., and question of change of personality, mental status, or behavior dating from some specific time or episode, which were of very frequent occurrence among our cases, appear to be of major seriousness from a clinical standpoint, especially in the sphere of personality deviation. In the conduct sphere their importance is also substantial, though not as an indicator of "juvenile delinquency" in the strict sense. Both notations were more characteristic of the older children among our group, especially question of change of personality.<sup>1</sup> Their correlations with chronological age, however, and with intelligence quotient (IQ), though positive, were low.<sup>2</sup>

Queer behavior was noted among 118, or 5.6 per cent, of our 2,113 White boys and among 67, or 5.7 per cent, of our 1,181 White girls.

Among boys its bi-serial correlation of  $.52 \pm .03$  with the personality-total was the highest of the 160 coefficients computed with this criterion,<sup>3</sup> being exceeded only by the correlations with the notations staff diagnosis or question of incipient psychosis (unspecified) and staff diagnosis or question of dementia praecox, which were of definitely pathological nature (Table 33). Among girls its bi-serial  $r$  of  $.61 \pm .03$  was the second highest coefficient, being exceeded by only one other coefficient among the 134 computed with this criterion. With the conduct-total criterion the boys' bi-serial  $r$  of  $.32 \pm .03$  indicated a mediocre association, but among girls its correlation of  $.64 \pm .03$  indicated a very meaningful relationship, being exceeded by only 8 of the 134 coeffi-

Leader.....	-.29 ± .05	.03
Feeble-minded sibling.....	-.23 ± .06	-.04

Other Correlations (Positive to Negative)

Bashful, .19 and .07; Victim of sex abuse, .19 (girls); Temper display, .18 and -.14; Underweight, .16 and .00; Spoiled child, .16 and .10; Truancy from home, .16 and .19; Lazy, .16 and .17; Inattentive in school, .15 and -.04; Egocentric, .15 and .18; Grouped: lack of interest in school, etc., .15 and .15; Nail-biting, .14 and .18; Finicky food habits, .13 and .04; Staying out late at night, .13 and .19; Slow, dull, .13 and -.01; Lack of initiative, .13 and .19; Immoral home conditions, .12 and -.04; Former convulsions, .12 and -.00; Teasing other children, .11 (boys); Sullen, .11 and .18; Stuttering, .10 (boys); Lack of interest in school, .10 and .18; Preference for younger children, .09

TABLE 33—Continued

and -.09; Question of hypophrenia, .09 and .02; Selfish, .08 and .19; Attractive manner, .07 and -.05; Vocational guidance, .07 and .03; Poor work in school, .06 and .08; Sex denied entirely, .06 and .10; Conduct prognosis bad, .06 and .09; Enuresis, .05 and .08; Smoking, .05 (boys); Sex delinquency (coitus), .04 and .17; Discord between parents, .03 and .11; Vicious home conditions, .02 and .16; Truancy from school, .02 and .13; Lues, .00 and .10; Irregular attendance at school, -.03 and -.09; Follower, -.06 and -.10; Brother in penal detention, -.06 and -.10; Retardation in school, -.08 and -.18; Gang, -.09 (boys); Clean, -.09 and .07; Popular, -.11 and .04

icients calculated with this criterion of seriousness.<sup>4</sup> For police arrest the tetrachoric correlations of .08  $\pm$  .04 and .19  $\pm$  .06 among boys and girls respectively indicated a low or negligible degree of relationship.

Among the separate notations its highest correlations among both boys and girls were .40  $\pm$  .05 and .53  $\pm$  .06 respectively with question of change of personality. Among girls there were seven additional high coefficients ranging from .40 to .46: violence, leading others into bad conduct, boastful or "show-off" manner, disobedience or incorrigibility (undifferentiated), irregular sleep habits, depressed spells, and changeable moods or attitudes, the corresponding correlations for boys ranging from -.02 to .25.

Three personality difficulties yielded substantial correlations ranging from .30 to .39 among both sexes: daydreaming, "nervousness", and object of teasing by other children. Overinterest in opposite sex (calculated for girls only) also yielded the substantial coefficient of .37  $\pm$  .06. Five notations yielded substantial coefficients ranging from .30 to .39 among boys and moderate coefficients in the .20's for girls: seclusiveness, absent-mindedness, inefficiency in work, play, etc., hatred or jealousy of sibling, and question or diagnosis of encephalitis. Six behavior traits among girls yielded substantial correlations in the .30's but moderate correlations in the .20's among boys: unpopularity, mental conflict, emotional instability, restlessness in sleep, quarrelsomeness, and swearing or bad language (undifferentiated). The following twelve conduct and personality difficulties yielded substantial correlations in the .30's among girls but low correlations below .20 for the boys: defiant attitude, temper

<sup>4</sup>Table 7 (p. 98).

tantrums, destructiveness, fighting, disturbing influence in school, stealing, lying, fantastical lying, rudeness, sulkiness, distractibility, and unhappiness.

The following five behavior traits showed moderate correlations in the .20's for both sexes: psychoneurotic trends, inferiority feelings, contrariness, stubbornness, and temper tantrums or display (undifferentiated). Complaining of bad treatment by other children and threatening violence, for which only the boys' coefficients were computed, also showed moderate correlations in the .20's. Six behavior notations among boys also showed moderate correlations in the .20's but low positive correlations ranging from .09 to .18 among girls: refusal to attend school, irritable temperament or disposition, apprehensiveness, listlessness, dull or slow manner (undifferentiated) and headaches. A large group of twenty-one miscellaneous notations showed moderate correlations in the .20's among girls but low or negligible correlations below .20 for the boys: restlessness, in corrigibility, disobedience, exclusion from school, bad companions, excuse-forming attitude, egocentricity or selfishness (undifferentiated), bossy manner, crying spells, sensitiveness in general, sensitiveness over some specific fact, worry over some specific fact, oversuggestibility, slovenliness, irresponsibility, loitering or wandering, repressed manner, masturbation, overinterest in sex matters, neurological defect (unspecified), and speech defect (other than stuttering).

Only two statistically significant negative correlations were found with queer behavior, both among boys:  $-.29 \pm .05$  for "leader" and  $-.23 \pm .06$  for feeble-minded sibling. The corresponding coefficients for girls were negligible.

Among the six sex notations, overinterest in opposite sex (calculated for girls only) yielded the substantial correlation of  $.37 \pm .06$  with queer behavior. Among girls overinterest in sex matters and masturbation also showed the moderate correlations of  $.20 \pm .07$  and  $.26 \pm .06$  respectively. The other notations in this field—sex delinquency (coitus), sex misbehavior denied entirely, and (calculated for girls only) victim of sex abuse—showed low coefficients ranging from .04 to .19.

Among the seven physical or psychophysical notations there were three instances in which correlations of moderate size were found. Question or diagnosis of encephalitis yielded correlations

of  $.30 \pm .10$  and  $.29 \pm .09$  for boys and girls respectively. Among girls neurological defect (unspecified) and speech defect (other than stuttering) showed moderate correlations of  $.21 \pm .07$  and  $.20 \pm .07$  respectively. The other notations in this field—enuresis, underweight condition, lues, and stuttering (calculated for boys only)—showed low positive coefficients ranging from .00 to .16.

The four home or familial notations—discord between parents, vicious and immoral home conditions, and brother in penal detention—showed only non-significant correlations ranging from  $-.10$  to  $.16$ .

Question of change of personality was noted in 123 cases, or 5.8 per cent of our boys, and among 65 cases, or 5.5 per cent of our girls. With personality-total its bi-serial correlations of  $.45 \pm .03$  and  $.53 \pm .03$  for boys and girls respectively indicate a high degree of clinical importance. Among girls its correlation with conduct-total was also high,  $.54 \pm .03$ , but among boys only moderate,  $.29 \pm .03$ . With the police-arrest criterion of "juvenile delinquency" its tetrachoric correlations were low and of little meaning.

Its highest correlations were with question or diagnosis of encephalitis for both boys and girls, the tetrachoric coefficients being  $.65 \pm .05$  and  $.66 \pm .07$  respectively (Table 34).

## Other Correlations (Positive to Negative)

Teasing other children, .19 (boys); Sensitive over specific fact, .17 and .19; Masturbation, .17 and .17; Sullen, .17 and .19; Quarrelsome, .17 and .16; Temper display, .15 and .09; Swearing (general), .14 (boys); Sensitive (general) .14 and .13; Repressed, .14 and .12; Victim of sex abuse, .14 (girls); Attractive manner, .14 and .06; Irregular attendance at school, .14 and .06; Grouped: dull, slow, etc., .13 and .04; Speech defect, .13 and .13; Threatening violence, .13 (boys); Nail-biting, .12 and .13; Gang, .12 (boys); Sulky, .12 and .17; Discord between parents, .11 and -.02; Slovenly, .10 and .15; Poor work in school, .09 and .06; Preference for younger children, .09 and .14; Boastful, "show-off," .08 and .14; Egocentric, .08 and .13; Underweight, .07 and -.02; Lack of initiative, .07 and -.12; Bashful, .07 and -.03; Popular, .06 and .19; Clean, .05 and .02; Excuse-forming, .05 and .15; Bossy, .04 and .19; Sex denied entirely, .03 and .17; Sex delinquency (coitus), .03 and .13; Bad companions, .02 and .19; Slow, dull, .02 and -.02; Question of hypophrenia, .02 and .15; Inattentive in school, .01 and .08; Former convulsions, .00 and .07; Overinterest in sex matters, -.00 and .13; Vicious home conditions, -.02 and .17; Lazy, -.02 and .09; Enuresis, -.04 and .07; Stuttering, -.05 (boys); Vocational guidance, -.05 and .00; Hatred or jealousy of sibling, -.06 and .12; Over-suggestible, -.08 and .16; Leader, -.09 and .07; Immoral home conditions, -.13 and .06; Retardation in school, -.15 and -.10

These correlations (which incidentally are also the highest coefficients found for question or diagnosis of encephalitis, as will be noted later in Table 117 [p. 542]) establish its importance as a clinical item, since it is an outstanding symptom of encephalitis

or encephalitic residual.<sup>5</sup> Changeable moods also showed the very high correlation of  $.62 \pm .04$  among boys and a substantial correlation among girls of  $.36 \pm .06$ .

Queer behavior among girls yielded the high correlation of  $.53 \pm .06$  and among boys a very substantial correlation of  $.40 \pm .05$ . Neurological defect (unspecified) and emotional instability among girls also yielded fairly high correlations of  $.42 \pm .06$  and  $.41 \pm .07$  respectively, with corresponding substantial correlations among boys of  $.36 \pm .05$  and  $.31 \pm .06$ . Unpopularity and temper tantrums among girls also yielded fairly high correlations of  $.43 \pm .08$  and  $.40 \pm .06$  respectively, with lower corresponding coefficients of  $.22 \pm .06$  and  $.19$  among boys.

Irregular sleep habits and crying spells yielded substantial correlations in the .30's for both sexes with question of change of personality. Irritable temperament and contrariness among boys also yielded substantial correlations in the .30's but somewhat lower corresponding coefficients for girls ( $.26 \pm .06$  and  $.15$ ). Five personality and conduct problems yielded substantial correlations in the .30's for girls and moderate coefficients in the .20's for boys: psychoneurotic trends, "nervousness," restlessness in sleep, depressed mood or spells, and disobedience. Fifteen additional conduct and personality problems yielded substantial correlations in the .30's for girls but low positive coefficients ranging from  $.03$  to  $.19$  among boys: distractibility, lack of interest in school, exclusion from school, disturbing influence in school, leading others into bad conduct, incorrigibility, destructiveness, violence, fighting, defiant attitude, truancy from home, staying out late at night, swearing or bad language (undifferentiated), fantastical lying, and "spoiled child."

The following seven notations showed correlations in the .20's with question of change of personality for both sexes: absent-mindedness, mental conflict, seclusiveness, object of teasing by other children, restlessness, refusal to attend school, and headaches. The two notations which were calculated for boys only, smoking and complaining of bad treatment by other children, and one calculated for girls only, overinterest in the opposite sex, also

---

<sup>5</sup>L. Jenkins and Luton Ackerson, "The Behavior of Encephalitic Children," American Journal of Orthopsychiatry, IV (1934), 499-507.

showed moderate coefficients in the .20's. The following four behavior difficulties among boys showed moderate correlations in the .20's but low positive coefficients below .20 for the girls: inferiority feelings, unhappiness, listlessness, and finicky food habits. The following fourteen behavior problems among girls showed moderate correlations in the .20's but low positive correlations below .20 for boys: sensitiveness or worrisomeness (undifferentiated), worry over specific fact, daydreaming, apprehensiveness, loitering or wandering, inefficiency in work, play, etc., irresponsibility, rudeness, selfishness, stubbornness, truancy from school, stealing, lying, and staff notation of unfavorable conduct prognosis.

Among four notations there were negative correlations of moderate size with question of change of personality, ranging from -.20 to -.24: feeble-minded sibling and "follower" among boys and brother in penal detention and lues among girls, the corresponding coefficients for the other sex being low, ranging from .03 to .11.

Among our six sex notations the only significant negative correlation was the moderate one of .23 + .06 with overinterest in opposite sex, which was calculated for girls only.

Among the physical or psychophysical notations there were three instances of meaningful correlation. Question or diagnosis of encephalitis, as we have seen, yielded the remarkably high tetrachoric coefficients of .65 + .05 and .66 + .07 for boys and girls respectively. Neurological defect (unspecified) yielded the very significant correlations of .36 + .05 and .42 + .06 for boys and girls respectively. These two neurological notations, it will be recalled, also showed meaningful correlations with queer behavior, as well as with question of change of personality. Diagnosis or question of lues among girls showed the barely significant negative correlation of -.20 + .07, this coefficient being not quite thrice its probable error. For enuresis, underweight condition, speech defect, and stuttering (calculated for boys only), the correlations were low for both sexes, ranging from -.05 to .13.

Among home and familial conditions the only correlation of significant size was the negative coefficient among girls of -.24 + .07 for brother in penal detention.

CHAPTER XXIV

CHANGEABLE MOODS AND EMOTIONAL INSTABILITY

Changeable, excitable moods and attitudes in our study was a case notation based upon a statement of the parent or other lay informant, while staff notation or question of emotional instability was a formal statement resulting from the clinical examination and was usually made by the psychiatrist. These two notations showed substantial to fairly high correlations ranging from .26 to .49 with both personality-total and conduct-total and are thus of some importance as clinical indications. With the police-arrest criterion the correlations with changeable moods were negligible, but those with emotional instability were of moderate size in the .20's.

Among our 2,113 White boys changeable moods was noted in 219 instances, or 10.4 per cent. Among our 1,181 White girls it was noted in 144 cases, or 12.2 per cent.

Its highest correlation was among boys,  $.62 \pm .04$  with question of change of personality, the girls' coefficient also being substantial,  $.36 \pm .06$  (Table 35). Its next highest coefficient

## Other Correlations (Positive to Negative)

Absent-minded, .18 and .02; Follower, .17 and .04; Irresponsible, .16 and .08; Teasing other children, .16 (boys); Slovenly, .16 and .08; Smoking, .16 (boys); Former convulsions, .16 and -.02; Inattentive in school, .15 and .09; Overinterest in sex matters, .15 and .03; Speech defect, .15 and .07; Swearing (general), .14 (boys); Apprehensive, .14 and .17; Disobedient, .13 and .12; Lying, .12 and .18; Stealing, .12 and .18; Enuresis, .11 and .01; Repressed, .07 and .03; Popular, .07 and .03; Gang, .06 (boys); Underweight, .06 and -.01; Lack of initiative, .05 and .05; Vicious home conditions, .05 and -.14; Bashful, .04 and .07; Refusal to attend school, .11 and -.03; Oversuggestible, .11 and .07; Listless, .09 and .07; Seclusive, .09 and .16; Grouped: lack of interest in school, etc., .09 and .18; Discord between parents, .08 and .04; Attractive manner, .04 and .02; Lazy, .03 and .01; Truancy from home, .03 and .17; Victim of sex abuse, .03 (girls); Poor work in school, .03 and .04; Grouped: dull, slow, etc., .02 and -.04; Sex delinquency (coitus), -.00 and .03; Bad companions, -.01 and .07; Staying out late at night, -.01 and .18; Mental conflict, -.01 and .15; Loitering, -.02 and .09; Truancy from school, -.02 and -.01; Slow, dull, -.04 and -.05; Stuttering, -.05 (boys); Vocational guidance, -.07 and -.01; Immoral home conditions, -.09 and -.02; Question of hypophrenia, -.10 and -.05; Lues, -.12 and .01; Retardation in school, -.13 and -.13; Irregular attendance at school, -.14 and -.01

Omitted—Grouped: "nervous," etc.

was among girls,  $.51 \pm .05$ , with depressed spells, the corresponding coefficient for boys,  $.28 \pm .04$ , being only moderate. Four behavior difficulties yielded substantial to fairly high correlations ranging from  $.30$  to  $.43$  among both sexes: irritable temperament, "nervousness," restlessness, and sensitiveness in general. The following thirteen case notations yielded substantial correlations ranging from  $.30$  to  $.43$  among girls and moderate correlations in the  $.20$ 's for boys: daydreaming, queer behavior, inefficiency in work, play, etc., psychoneurotic trends, fantastical lying, restless in sleep, sensitiveness or worrisomeness (undifferentiated), crying spells, contrariness, rudeness, violence, temper tantrums, and neurological defect (unspecified). Ten case notations showed substantial correlations ranging from  $.30$  to  $.42$  among girls but low positive coefficients ranging from  $.09$  to  $.19$  among boys: question or diagnosis of encephalitis, boastful or "show-off" manner, swearing or bad language (undifferentiated), bossy manner, fighting, selfishness, unpopularity, sulkiness, emotional instability, and irregular sleep habits.

Changeable moods showed moderate correlations in the  $.20$ 's among both sexes for the following six behavior problems: temper display, quarrelsomeness, disobedience or incorrigibility (undifferentiated), excuse-forming attitude, nail-biting, and masturbation. Also overinterest in the opposite sex (computed for girls only) and two other notations, threatening violence and complaining of bad treatment by other children (calculated for boys only), showed moderate correlations in the  $.20$ 's. Finicky food habits among boys showed the moderate correlation of  $.24 \pm .04$  but among girls the low correlation of  $.12$ . Among girls a large group of twenty-four case notations showed moderate correlations in the  $.20$ 's but low coefficients ranging from  $-.13$  to  $.18$  among boys: destructiveness, defiant attitude, stubbornness, incorrigibility, sullenness, leading others into bad conduct, exclusion from school, disturbing influence in school, lack of interest in school, distractibility, egocentricity, hatred or jealousy of sibling, "spoiled child," unhappiness, inferiority feelings, sensitiveness over specific fact, worry over specific fact, preference for younger children as playmates, object of teasing by other children, sex misbehavior denied entirely, staff notation of unfavorable conduct prognosis, headaches, "leader," and clean habits.

The only considerable negative correlation with changeable moods was the moderate one of  $-.25 \pm .05$  among girls with brother in penal detention, the corresponding boys' coefficient being  $-.12$ .

Among the sex notations masturbation showed moderate correlations in the .20's for both sexes. Overinterest in opposite sex, which was calculated for girls only, yielded a moderate correlation of  $.28 \pm .05$ . Sex misbehavior denied entirely among girls showed the moderate correlation of  $.21 \pm .07$ , while among boys the correlation was negative,  $-.13$ . Sex delinquency (coitus), overinterest in sex matters, and (calculated for girls only) victim of sex abuse yielded only negligible correlations.

Among the seven physical or psychophysical case notations the only significant indications were for question or diagnosis of encephalitis, which yielded the coefficients of  $.39 \pm .07$  among girls with a negligible coefficient of  $.09$  among boys, and for neurological defect (unspecified), which yielded coefficients of  $.20 \pm .04$  and  $.33 \pm .05$  for boys and girls respectively.

Among home or familial notations the only correlation of significant size with changeable moods was the negative one of  $-.25 \pm .05$  among girls for brother in penal detention.

Staff notation or question of emotional instability or emotional lability yielded correlations bearing considerable similarity to those for changeable moods, one point of difference, however, being that emotional instability among both sexes showed moderate correlations in the .20's with the police-arrest criterion, while changeable moods indicated an essentially zero relationship. Emotional instability was noted among 104, or 4.9 per cent, of our boys and among 85, or 7.2 per cent, of our girls.

Its highest correlation among both sexes was with question or diagnosis of encephalitis, the tetrachoric coefficients being  $.46 \pm .06$  and  $.48 \pm .08$  (Table 36). Staff notation of unfavorable conduct prognosis among boys also yielded the fairly high correlation of  $.40 \pm .06$  with the substantial correlation of  $.32 \pm .07$  among girls. Three personality notations also yielded similar correlations ranging from  $.47$  down to  $.41$  among girls: psychoneurotic trends, question of change of personality, and restlessness, the corresponding coefficients for boys ranging from  $.31$  down to  $.21$ . Violence and "nervousness" or restlessness (including irritable

## Other Correlations (Positive to Negative)

Stealing, .18 and .09; Refusal to attend school, .17 and .04; Worry over specific fact, .16 and .14; Contrary, .16 and .08; Bad companions, .15 and .17; Slovenly, .15 and .07; Irregular attendance at school, .14 and -.01; Masturbation, .14 and .16; Defiant, .14 and .18; Speech defect, .13 and .07; Inferiority feelings, .12 and .17; Overinterest in sex matters, .12 and .13; Restless in sleep, .11 and -.02; Grouped: egocentric, etc., .11 and .17; Stuttering, .10 (boys); Sulky, .10 and .14; Stubborn, .10 and .15; Gang, .10 (boys); Finicky food habits, .10 and .06; Truancy from home, .09 and .18; Sensitive (general), .09 and .13; Leader, .08 and .11; Apprehensive, .08 and .16; Threatening violence, .08 (boys); Swearing (general), .08 (boys); Disobedient, .08 and .19; Sullen, .07 and .17; Lues, .07 and -.01; Immoral home conditions, .07 and -.01; Unhappy, .06 and .16; Seclusive, .06 and .11; Lack of interest in school, .05 and .08; Truancy from school, .05 and .13; Oversuggestible, .05 and .06; Discord between parents, .05 and .01; Former convulsions, .04 and -.05; Sex delinquency (coitus), .04 and .17; Lazy, .03 and .09; Follower, .03 and -.06; Grouped: lack of interest in school, etc., .03 and .07; Smoking, .02 (boys); Enuresis, .02 and .08; Listless, .01 and -.02; Question of hypophrenia, .01 and -.07; Poor work in school, -.01 and -.02; Attractive manner, -.02 and .10; Inattentive in school, -.03 and -.04; Popular, -.03 and .11; Victim of sex abuse, -.03 (girls); Hatred or jealousy of sibling, -.04 and .15; Underweight, -.04 and .10; Nail-biting, -.06 and .13; Feeble-minded sibling, -.07 and .15; Preference for younger children, -.07 and .06; Bashful, -.08 and -.04; Vocational guidance, -.08 and -.04; Clean, -.10 and .07; Retardation in school, -.10 and -.17; Selfish, -.11 and .08; Grouped: dull, slow, etc., -.13 and -.16; Teasing other children, -.13 (boys); Slow, dull, -.17 and -.15; Sex denied entirely, -.18 and -.03

temperament and changeable moods, undifferentiated) yielded substantial correlations in the .30's for both boys and girls. The following six notations among girls yielded substantial correlations in the .30's, with corresponding moderate coefficients in the .20's for boys: crying spells, temper tantrums, queer behavior, fantastical lying, inefficiency in work, play, etc., and exclusion from school. The following nine behavior problems also yielded substantial correlations in the .30's for girls but low positive coefficients below .20 for boys: changeable moods, "spoiled child," boastful or "show-off" manner, daydreaming, sensitiveness or worrisomeness (undifferentiated), unpopularity, destructiveness, leading others into bad conduct, and irregular sleep habits.

The following seven case notations showed moderate correlations in the .20's with emotional instability for both sexes: irritable temperament, "nervousness," quarrelsomeness, fighting, incurability, depressed spells, and neurological defect (unspecified), and also complaining of bad treatment by other children, which was computed for boys only. The following six notations among boys also showed moderate correlations in the .20's but low coefficients below .20 for the girls: temper display, staying out late at night, loitering or wandering, absent-mindedness, object of teasing by other children, and vicious home conditions. The following twelve notations among girls also showed moderate correlations below .20 for the boys: mental conflict, sensitiveness over specific fact, excuse forming attitude, irresponsibility, egocentricity, bossy manner, rudeness, distractibility, lying, swearing or bad language (undifferentiated), disturbing influence in school, and headaches. Overinterest in opposite sex, for which only the girls' correlation was computed, also showed a moderate correlation of  $.23 \pm .05$ .

There were three negative correlations of significant size with emotional instability: among boys repressed manner showed the moderate coefficient of  $-.26 \pm .06$ , the corresponding correlation among girls being only .06. Lack of initiative or ambition among girls yielded a correlation of  $-.30 \pm .07$ , while among boys its correlation was .06. Vicious home conditions showed a curious divergence in its correlations, the coefficient for girls being a negative  $-.20 \pm .07$ , while among boys it was a positive  $.21 \pm .07$ .

Among the six sex notations the only correlation of significant size was  $.23 \pm .05$  for overinterest in opposite sex (calculated for girls only). For masturbation the two coefficients of  $.14$  and  $.16$  may be suggestive but were below the conventional standard of "statistical significance."

Among the seven physical or psychophysical notations we have already noted the striking correlations of  $.46 \pm .06$  and  $.48 \pm .08$  with question or diagnosis of encephalitis and also the moderate correlations of  $.29 \pm .05$  and  $.25 \pm .06$  with neurological defect (unspecified). The other five notations in this field (enuresis, underweight condition, diagnosis or question of lues, speech defect, and stuttering) showed only negligible correlations with emotional instability.

Among the four home or familial notations the only coefficients of significant size were the two seemingly contradictory correlations with vicious home conditions ( $.21 \pm .07$  and  $-.20 \pm .07$  for boys and girls respectively).

## CHAPTER XXV

### SUSPECTED MENTAL DEFICIENCY (HYPOPHRENIA)

Question of mental deficiency, hypophrenia, or inadequate intelligence in the present data is not a staff notation but indicates the "lay" opinion expressed by a parent, friend, teacher, employer, or a social agency not equipped with psychological or psychiatric service sufficient to render a formal diagnosis. This notation does not always indicate a patent mental deficiency but may occasionally mean an intellectual capacity too low for the given school studies or employment of the patient at the time of examination. For example, a fourth-year high-school student may be handicapped by "inadequate intelligence" and still be far from "mentally deficient." (In fact, among the 3,294 boys and girls considered in the present volume, 23 with IQ's of 100 or more were so noted, one of whom achieved a Stanford-Binet IQ above 125.) The coefficients in Table 37 should therefore be carefully contrasted with those for intelligence quotient (IQ).<sup>1</sup>

Question of hypophrenia was noted among 454 of our 2,113 White boys, or 21.5 per cent, and among 283 of our 1,181 White girls, or 24.0 per cent, and was one of the most frequent reasons for which children were referred for examination in this clinic.<sup>2</sup>

The correlations of question of hypophrenia with our three criteria of seriousness or "ominousness" (personality-total, conduct-total, and police arrest) were very low, ranging from -.15 to .04 (Table 37). In this connection it should be pointed out that question of hypophrenia was not counted in the personality-total because its inclusion would probably have weighted the personality-total too much in the direction of low intelligence, especially since another similar notation, slow or dull manner, was already included in the personality-total. Following the conventional

.04 and .01; Grouped: fighting, etc., .03 and .02; Neurological defect, .03 and .09; Leading others into bad conduct, .03 and .14; Teasing other children, .02 (boys); Question of change of personality, .02 and .15; "Nervous," .02 and .01; Stuttering, .02 (boys); Grouped: temper, etc., .02 and .02; Emotional instability, .01 and -.07; Slovenly, .01 and .08; Disobedient, .01 and .04; Destructive, .00 and .11; Temper tantrums, .00 and .02; Inefficient in work, play, etc., -.00 and .04; Refusal to attend school, -.00 and -.07; Sullen, -.00 and .05; Listless, -.00 and .08; Grouped: swearing, etc., -.01 and .03; Vicious home conditions, -.01 and .16; Spoiled child, -.01 and .08; Sex delinquency (coitus), -.01 and -.08; Staying out late at night, -.01 and -.04; Disturbing influence in school, -.01 and .12; Contrary, -.02 and -.01; Fighting, -.02 and -.06; Lack of interest in school, -.02 and .04; Irregular sleep habits, -.02 and .06; Unpopular, -.02 and .11; Masturbation, -.03 and .00; Truancy from school, -.03 and -.06; Truancy from home, -.03 and -.05; Quarrelsome, -.03 and .06; Nail-biting, -.03 and .06; Overinterest in opposite sex, -.03 (girls); Crying spells, -.04 and .06; Irritable, -.04 and -.04; Attractive manner, -.04 and -.18; Grouped: "nervous," etc., -.04 and .04; Grouped: lack of interest in school, etc., -.05 and -.03; Sensitive (general), -.05 and -.08; Restless, -.05 and .05; Finicky food habits, -.06 and -.15; Lying, -.06 and -.08; Grouped: disobedient, etc., -.06 and -.01; Inferiority feelings, -.06 and -.07; Grouped: depressed, etc., -.07 and -.13; Stubborn, -.07 and -.08; Gang, -.07 (boys); Inattentive in school, -.07 and -.15; Bad companions, -.07 and -.16; Boastful, "show-off," -.08 and -.05; Rude, -.08 and -.12; Stealing, -.08 and -.08; Popular, -.08 and -.14; Victim of sex abuse, -.09 (girls); Mental conflict, -.10 and -.18; Changeable moods, -.10 and -.05; Lazy, -.10 and .06; Irresponsible, -.10 and .01; Bossy, -.11 and -.05; Daydreaming, -.11 and -.15; Excuse-forming, -.11 and -.05; Sex denied entirely, -.11 and -.01; Leader, -.11 and .19; Discord between parents, -.11 and -.11; Clean, -.12 and -.17; Smoking, -.13 (boys); Defiant, -.19 and -.11; Grouped: sensitive or worrisome, etc., -.15 and -.09; Unhappy, -.16 and -.03; Sensitive over specific fact, -.16 and -.08

beliefs, we have listed it as "physical or constitutional defect" in our indexing of the original case-record material.<sup>3</sup>

The highest correlations with question of hypophrenia among both sexes were with intelligence quotient (IQ), which yielded the negative bi-serial  $r$  of  $-.57 \pm .02$  and  $-.53 \pm .02$  as noted in chapter xiii. The next highest correlations were the positive tetrachoric  $r$ 's of  $.55 \pm .02$  and  $.48 \pm .03$  for boys and girls respectively with retardation in school.

With the specific behavior and other notations there were relatively few correlations of statistically significant size. The coefficients were about equally divided between positive and negative signs. The following three notations among both sexes yielded moderate positive coefficients ranging from .20 to .29: slow or

<sup>3</sup>I, 73-76, Table 6.

dull manner, poor work in school, and feeble-minded sibling. Moderate negative correlations of  $-.29 \pm .04$  and  $-.21 \pm .05$  were found for psychoneurotic trends among boys and girls respectively.

Speech defect and staff notation of unfavorable conduct prognosis among boys showed moderate positive correlations in the .20's but corresponding low correlations below .20 among girls. Worry over some specific fact or episode among boys showed the moderate negative correlation of  $-.23 \pm .04$  and among girls the low negative coefficient of  $-.10$ . The following four notations among girls showed moderate positive correlations ranging from .22 to .32 but low positive correlations below .20 for boys: preference for younger children as playmates, exclusion from school, underweight condition, and lues. The following eight notations showed moderate negative tetrachoric correlations in the  $-.20$ 's among girls, the corresponding coefficients for boys being negative and low, ranging from  $-.01$  to  $-.19$ : selfishness, egocentricity, hatred or jealousy of sibling, depressed spells, repressed manner, overinterest in sex matters, immoral home conditions, and "request for vocational guidance."

Among our six sex notations the only correlation of significant size with question of hypophrenia was the negative of  $-.22 \pm .05$  among girls with overinterest in sex matters. All the other correlations in this field were a low negative, ranging from .00 to  $-.11$ .

Among the seven physical or psychophysical traits there were three instances in which the correlations were of statistically significant size. Among girls underweight condition and lues showed moderate correlations of  $.25 \pm .04$  and  $.22 \pm .05$  respectively. Speech defect (other than stuttering) showed the moderate correlation of  $.22 \pm .04$  for boys. The remaining coefficients in this field were low, ranging from .02 to .16.

Among the four home or familial notations there was only one coefficient of significant size,  $-.24 \pm .05$  among girls for immoral home conditions, the other correlations in this field ranging from  $-.19$  to .16.

Since question of hypophrenia is the "opposite" of intelligence quotient (IQ), a comparison of the coefficients (chiefly tetrachoric  $r$ 's) in Table 37 with those for IQ (chiefly bi-serial  $r$ 's)

is interesting. The intercolumnar product-moment correlations were  $-.81 \pm .02$  and  $-.57 \pm .04$  for boys and girls respectively. Among the 120 pairs of boys' coefficients, 83 pairs were of unlike sign and only 37 were of like sign. Among 115 pairs of coefficients among girls, 69 were of unlike sign, and 46 were of like sign. If both measures were truly valid measures of intelligence (or lack of intelligence), the intercolumnar correlations should approach a negative unity. In view of the inadequacies in both measures, especially those due to the subjectivity of the "lay" notation of question of mental deficiency or inadequate intelligence, these intercolumnar correlations are probably as satisfactory as may be expected. (This phenomenon of inconsistency in the correlations of antithetical traits has been discussed in I, 134-35 and 249-50, and this volume, pp. 45 and 204-5.)

## CHAPTER XXVI

### SLOW OR DULL MANNER; LISTLESSNESS; LACK OF INITIATIVE

The three generally similar personality problems—slow or dull manner, listlessness or indifferent attitude, and lack of initiative or ambition—showed a moderate degree of intercorrelation with one another and also general similarity in their correlations with "outside" traits. All three appear to be of little importance as far as their correlations with our three criteria of "seriousness" indicate, the correlation coefficients ranging from  $-.16$  to  $.19$ .

Slow or dull manner was noted among 541 of our 2,113 White boys, or 25.6 per cent, and 285 of our 1,181 White girls, or 24.1 per cent. It was one of the most often noted of behavior traits among our case records. It was significantly correlated with low intelligence, the correlation with intelligence quotient for boys and girls being, respectively,  $-.26 \pm .04$  and  $-.24 \pm .03$  (Table 10, p. 130).<sup>1</sup>

Of the many correlations computed, only a comparative few were of statistically significant size. Its largest correlations were for listlessness among both boys and girls, the respective coefficients being  $.31 \pm .03$  and  $.28 \pm .05$ , and for retardation in school with corresponding correlations of  $.24 \pm .03$  and  $.30 \pm .03$  (Table 38). Other correlations of moderate size in the .20's among both sexes were for question of hypophrenia, distractibility, and absent-mindedness. Poor work in school and speech defect among boys showed moderate correlations in the .20's, with corresponding low correlations below .20 among girls. Four notations among girls showed moderate correlations in the .20's, the corresponding coefficients for boys ranging from .07 to .18: lack of initiative,

ings, -.03 and -.01; Grouped: "nervous," etc., -.03 and -.02; Sensitive over specific fact, -.04 and -.02; Changeable moods, -.04 and -.05; Masturbation, -.04 and -.05; Staying out late at night, -.04 and -.13; Leading others into bad conduct, -.04 and -.04; Fantastical lying, -.04 and -.03; Defiant, -.04 and -.06; Bossy, -.04 and .01; Smoking, -.05 (boys); Irritable, -.05 and -.01; Unpopular, -.05 and -.02; Grouped: egocentric, etc., -.05 and -.06; Grouped: swearing, etc., -.06 and .03; Overinterest in sex matters, -.06 and -.14; Temper display, -.06 and .07; Disobedient, -.06 and -.13; Destructive, -.07 and .00; Nail-biting, -.07 and -.08; Quarrelsome, -.07 and .03; Grouped: disobedient, etc., -.07 and -.03; Grouped: temper, etc., -.07 and .06; Grouped: fighting, etc., -.08 and .03; Exclusion from school, -.08 and -.06; Spoiled child, -.08 and .08; Fighting, -.08 and .05; Bad companions, -.08 and -.15; Finicky food habits, -.09 and -.12; Rude, -.09 and -.12; Truancy from home, -.09 and -.04; Egocentric, -.09 and -.10; Sex delinquency (coitus), -.09 and .01; Contrary, -.10 and -.07; Disturbing influence in school, -.11 and .05; Violence, -.11 and .09; Clean, -.11 and .06; Victim of sex abuse, -.11 (girls); Overinterest in opposite sex, -.11 (girls); Gang, -.12 (boys); Incurable, -.12 and -.10; Temper tantrums, -.14 and .05; Leader, -.17 and -.14; Emotional instability, -.17 and -.15; Boastful, "show-off," -.17 and -.03; Psychoneurotic, -.19 and -.12

Omitted—Grouped: dull, slow, etc.

inefficiency in work, play, etc., preference for younger children as playmates, and feeble-minded sibling.

Among the seventeen notations given special discussion (sex, physical or psychophysical, and home or familial) only one notation showed a meaningful correlation—speech defect (other than stuttering), the coefficients for boys and girls being  $.21 \pm .03$  and  $.17$  respectively.

Listlessness or attitude of indifference was noted among 178 boys, or 8.4 per cent, and among 87 girls, or 7.4 per cent.

Its highest correlation was among girls,  $.41 \pm .06$  with seclusiveness, the corresponding coefficients for boys also being substantial,  $.34 \pm .04$  (Table 39). Laziness among boys yielded the substantial coefficient of  $.36 \pm .04$ , the corresponding coefficient among girls,  $.24 \pm .07$ , being moderate. Two personality notations showed substantial correlations of  $.31$  each among boys, slow or dull manner and absent-mindedness, the corresponding coefficients for girls being  $.28 \pm .05$  and  $.05$  respectively. Two additional substantial correlations in the .30's were found among girls, contrariness and leading others into bad conduct, the boys' correlations being negligible,  $.08$  and  $-.07$  respectively.

Six notations showed moderate correlations in the .20's

Psychoneurotic, .17 and .15; Irritable, .15 and -.11; Sensitive over specific fact, .15 and .01; Mental conflict, .14 and .05; Restless in sleep, .14 and .06; Refusal to attend school, .14 and -.06; Lack of interest in school,

TABLE 39—Continued

.14 and .16; Restless, .13 and .17; Unhappy, .13 and .13; Stuttering, .13 (boys); Speech defect, .13 and .15; Discord between parents, .13 and -.08; Grouped: sensitive or worrisome, etc., .13 and -.03; Underweight, .12 and -.06; Apprehensive, .12 and -.10; Teasing other children, .12 (boys); Finicky food habits, .12 and .10; Enuresis, .11 and .18; Masturbation, .11 and .00; Overinterest in opposite sex, .11 (girls); Grouped: temper, etc., .10 and -.00; Changeable moods, .09 and .07; "Nervous," .09 and -.04; Spoiled child, .08 and -.01; Crying spells, .08 and .09; Smoking, .08 (boys); Sulky, .07 and .09; Sullen, .07 and .15; Irregular sleep habits, .07 and -.04; Immoral home conditions, .07 and .02; Popular, .06 and -.10; Loitering, .05 and .02; Object of teasing, .05 and -.01; Oversuggestible, .05 and .19; Grouped: egocentric, etc., .04 and .11; Grouped: fighting, etc., .04 and .05; Egocentric, .04 and .03; Threatening violence, .04 (boys); Nail-biting, .04 and -.17; Defiant, .04 and .11; Fighting, .03 and .16; Quarrelsomeness, .03 and .01; Overinterest in sex matters, .03 and -.10; Vocational guidance, .03 and .07; Inferiority feelings, .02 and .02; Former convulsions, .02 and -.12; Sex delinquency (coitus), .02 and .01; Rude, .02 and .05; Sensitive (general), .01 and .05; Emotional instability, .01 and -.02; Complaining of bad treatment by other children, .01 (boys); Brother in penal detention, .01 and .05; Feeble-minded sibling, .01 and .13; Stealing, .00 and .08; Selfish, .00 and .11; Destructive, .00 and .09; Excuse-forming, -.00 and -.03; Victim of sex abuse, -.00 (girls); Question of hypophrenia, -.00 and .08; Follower, -.00 and .05; Temper display, -.01 and -.07; Stubborn, -.01 and .17; Fantastical lying, -.01 and .02; Disturbing influence in school, -.02 and .10; Staying out late at night, -.02 and -.09; Swearing (general), -.02 (boys); Exclusion from school, -.02 and .05; Retardation in school, -.02 and -.01; Clean, -.02 and .13; Grouped: swearing, etc., -.02 and .05; Vicious home conditions, -.03 and -.00; Hatred or jealousy of sibling, -.03 and .04, Boastful, "show-off," -.03 and .14; Bad companions, -.04 and -.13; Temper tantrums, -.04 and .07; Sex denied entirely, -.05 and .15; Truancy from home, -.05 and -.10; Lying, -.07 and .02; Disobedient, -.07 and .03; Incurable, -.08 and -.03; Grouped: disobedient, etc., -.08 and .16; Irregular attendance at school, -.09 and -.07; Unpopular, -.09 and .17; Gang, -.09 (boys); Truancy from school, -.10 and -.09; Lues, -.14 and -.02; Leader, -.15 and -.14; Bossy, -.16 and -.10

Omitted—Grouped: dull, slow, etc.

with listlessness for both sexes: inefficiency in work, play, etc. lack of initiative, daydreaming, poor work in school, distractibility, and depressed spells. Seven notations showed moderate correlations in the .20's for the boys but low correlations ranging from -.16 to .18 among girls: question or diagnosis of encephalitis, queer behavior, question of change of personality, bashfulness, irresponsibility, "nervousness" or restlessness (undifferentiated), and headaches. Seven notations among girls showed moderate correlations in the .20's, with low positive correlations below .20 for the boys: inattentiveness in school, slovenliness, repressed manner, preference for younger children as playmates, violence, staff notation of unfavorable conduct prognosis, and neurological defect (unspecified).

There were two negative correlations of significant size,

both among girls, attractive manner,  $-.34 \pm .05$ , and worry over some specific fact,  $-.25 \pm .08$ , the corresponding coefficients for boys being low, .06 and .13 respectively.

Among the sex notations and also among the home or familial conditions there were no coefficients of significant size.

Among physical notations we have noted the moderate correlations of  $.27 \pm .06$  for question or diagnosis of encephalitis among boys and  $.20 \pm .06$  with neurological defect (unspecified) among girls.

Lack of initiative or ambition ("patient is unaggressive, lacks energy") was noted among 132 boys, or 6.2 per cent, and among 63 girls, or 5.3 per cent.

Its highest correlation was noted among boys,  $.39 \pm .04$ , with inattentiveness in school, the corresponding coefficient among girls being negligible (Table 40).

## Other Correlations (Positive to Negative)

Irresponsible, .19 and .08; Clean, .18 and .06; Lack of interest in school, .17 and .06; Sensitive over specific fact, .17 and -.19; Preference for younger children, .17 and .10; Stuttering, .17 (boys); Grouped: "nervous," etc., .16 and .00; Neurological defect, .16 and -.12; Mental conflict, .16 and -.04; Worry over specific fact, .15 and -.15; Inferiority feelings, .15 and .11; Spoiled child, .15 and .00; Discord between parents, .14 and .09; Object of teasing, .14 and -.11; Apprehensive, .14 and -.03; Irritable, .13 and -.12; Distractible, .13 and .04; Oversuggestible, .13 and .17; Queer, .13 and .19; Grouped: lack of interest in school, etc., .13 and .03; Grouped: depressed, etc., .12 and -.08; Speech defect, .12 and .01; Slovenly, .12 and .12; Stubborn, .11 and -.02; Violence, .09 and -.18; Question of hypochondria, .09 and .10; Popular, .09 and -.07; Attractive manner, .08 and .04; Finicky food habits, .08 and .11; Enuresis, .08 and .05; Question of change of personality, .07 and -.12; Restless, .06 and .01; Loitering, .05 and -.11; Refusal to attend school, .05 and -.18; Temper tantrums, .05 and -.13; Changeable moods, .05 and .05; Crying spells, .05 and -.04; Irregular attendance at school, .05 and -.02; Depressed, .05 and .01; Repressed, .04 and .13; Staying out late at night, .04 and -.06; "Nervous," .03 and -.05; Hatred or jealousy of sibling, .02 and .13; Nail-biting, .02 and .03; Headaches, .01 and -.10; Former convulsions, .01 and -.06; Grouped: egocentric, etc., .01 and -.07; Restless in sleep, .00 and .11; Masturbation, .00 and -.13; Sulky, .00 and -.04; Threatening violence, -.00 (boys); Feeble-minded sibling, -.00 and .03; Grouped: disobedient, etc., -.01 and -.03; Leader, -.01 and -.11; Contrary, -.02 and .03; Sullen, -.02 and -.13; Temper display, -.02 and -.12; Truancy from school, -.02 and -.11;

TABLE 40—Continued

Immoral home conditions, -.03 and .07; Underweight, -.03 and -.11; Complaining of bad treatment by other children, -.03 (boys); Victim of sex abuse, -.03 (girls); Lies, -.05 and -.03; Excuse-forming, -.05 and -.01; Teasing other children, -.05 (boys); Fighting, -.05 and .02; Defiant, -.05 and .05; Lying, -.06 and -.02; Quarrelsome, -.06 and -.06; Truancy from home, -.06 and -.03; Retardation in school, -.06 and -.06; Grouped: fighting, etc., -.07 and -.07; Overinterest in sex matters, -.07 and -.17; Rude, -.07 and -.13; Egocentric, -.08 and .12; Leading others into bad conduct, -.09 and -.06; Incurable, -.09 and -.14; Fantastical lying, -.09 and .11; Bad companions, -.10 and -.15; Disobedient, -.10 and -.06; Gang, -.11 (boys); Stealing, -.12 and -.01; Brother in penal detention, -.13 and .03; Smoking, -.14 (boys); Exclusion from school, -.16 and .07; Vicious home conditions, -.17 and -.13  
Omitted—Grouped: dull, slow, etc.

Five behavior traits showed moderate correlations in the .20's for both sexes: listlessness, laziness, absent-mindedness, daydreaming, and poor work in school. Six notations showed moderate correlations in the .20's among boys but low correlations ranging from -.01 to .19 among girls: inefficiency in work, play, etc., bashfulness, seclusiveness, sensitiveness in general, selfishness, and "request for vocational guidance." Three notations among girls showed moderate correlations in the .20's but low positive correlations below .18 for boys: slow or dull manner, irregular sleep habits, and "follower."

There was a large group of behavior notations showing moderate negative correlations ranging from -.20 to -.30 with lack of initiative. Among boys these were disturbing influence in school, sex delinquency (coitus), and (calculated for boys only) swearing (general). Among girls similar negative coefficients were found for emotional instability, unhappiness, unpopularity, bossy manner, temper tantrums or display (undifferentiated), swearing or bad language (undifferentiated), staff notation of unfavorable conduct prognosis, and (calculated for girls only) overinterest in opposite sex.

There were five notations for which tetrachoric correlations could not be computed among girls because there were no instances in which girls noted as lacking initiative had a notation in the following items: psychoneurotic trends, boastful or "show-off" manner, destructiveness, sex misbehavior denied entirely, and question or diagnosis of encephalitis.

Among the six sex notations there were two instances in

which significant correlations were found, both being negative: for sex delinquency (coitus) among boys,  $-.20 \pm .07$ , and for over-interest in opposite sex, which was calculated only among the girls,  $-.23 \pm .06$ .

Among the physical, psychophysical, and home or familial notations there were no correlations of significant size.

When the cases falling under the rubrics slow or dull manner, listlessness, and lack of initiative or ambition were combined into one large grouping, there were 704 boys, or 33.3 per cent, and 364 girls, or 30.8 per cent, so noted. The correlation coefficients based upon this broader grouping, as shown in Table 41, are generally similar to those previously presented in Table 38 (slow

TABLE 41—Continued

## Other Correlations (Positive to Negative)

Depressed, .19 and .08; Bashful, .18 and .14; Daydreaming, .18 and .14; Grouped: depressed, etc., .17 and .01; Apprehensive, .15 and .03; Irresponsible, .15 and -.03; Worry over specific fact, .13 and -.17; Object of teasing, .13 and .05; Question of change of personality, .13 and .04; Slovenly, .13 and .15; Question of encephalitis, .13 and -.08; Headaches, .12 and -.02; Follower, .12 and .15; Oversuggestible, .12 and .15; Unhappy, .11 and .01; Neurological defect, .11 and .01; Grouped: lack of interest in school, etc., .10 and .10; Mental conflict, .10 and -.12; Lack of interest in school, .09 and .17; Vocational guidance, .09 and .08; Grouped: sensitive or worrisome, etc., .08 and -.02; Disobedient, .08 and -.14; Crying spells, .08 and -.02; Restless in sleep, .07 and .09; Stubborn, .07 and -.02; Inattentive in school, .07 and .03; Enuresis, .07 and .04; Discord between parents, .06 and -.01; Underweight, .06 and -.02; Sensitive (general), .06 and .07; Sex denied entirely, .06 and -.07; Sensitive over specific fact, .05 and -.05; Temper display, .05 and .03; Refusal to attend school, .05 and -.12; Grouped: "nervous," etc., .04 and .01; Selfish, .04 and -.07; Sullen, .04 and .07; Irregular sleep habits, .04 and .07; Inferiority feelings, .03 and .05; Excuse-forming, .03 and .02; Threatening violence, .03 (boys); Teasing other children, .03 (boys); Former convulsions, .03 and -.15; Irregular attendance at school, .02 and -.01; Finicky food habits, .02 and -.02; Sulky, .02 and .06; Changeable moods, .02 and -.04; Irritable, .02 and -.04; Attractive manner, .02 and -.11; Stuttering, .01 (boys); Complaining of bad treatment by other children, .01 (boys); Loitering, .01 and .00; Vicious home conditions, .01 and -.00; Immoral home conditions, .00 and -.02; Brother in penal detention, .00 and .01; Truancy from school, .00 and -.09; Restless, -.00 and .11; Conduct prognosis bad, -.00 and .16; Lues, -.00 and .03; "Nervous," -.01 and -.02; Grouped: temper, etc., -.01 and -.00; Psychoneurotic, -.01 and -.16; Swearing (general), -.01 (boys); Masturbation, -.01 and -.12; Hatred or jealousy of sibling, -.01 and -.09; Grouped: egocentric, etc., -.02 and -.03; Bossy, -.02 and -.07; Clean, -.03 and .07; Stealing, -.03 and -.02; Fantastical lying, -.03 and -.01; Leading others into bad conduct, -.04 and -.05; Staying out late at night, -.04 and -.12; Popular, -.04 and -.09; Nail-biting, -.05 and -.07; Defiant, -.05 and -.01; Contrary, -.05 and .06; Grouped: swearing, etc., -.06 and .01; Lying, -.02; Smoking, -.06 (boys); Egocentric, -.06 and -.06; Temper tantrums, -.07 and -.00; Rude, -.07 and -.08; Fighting, -.07 and .12; Destructive, -.07 and -.00; Bad companions, -.07 and -.16; Grouped: fighting, etc., -.07 and .05; Overinterest in opposite sex, -.07 (girls); Grouped: disobedient, etc., -.08 and -.00; Quarrelsome, -.08 and .04; Violence, -.08 and .08; Truancy from home, -.08 and -.05; Unpopular, -.08 and -.02; Exclusion from school, -.09 and .01; Boastful, "show-off," -.10 and -.01; Sex delinquency (coitus), -.11 and -.15; Disturbing influence in school, -.11 and .04; Gang, -.11 (boys); Victim of sex abuse, -.11 (girls); Incurable, -.13 and -.08; Emotional instability, -.13 and -.16; Leader, -.17 and -.17

Omitted—Slow, dull; Listless; Lack of initiative

or dull manner) for the simple reason that over three-quarters of the cases appearing in the broader grouping, dull or slow manner (including listlessness and lack of initiative, undifferentiated), were also placed under the specific group of slow or dull manner,<sup>2</sup>

<sup>2</sup>The reasons for this broader grouping were given in I, 44, and 86, Table 13, Item D.

and the material of the two tables (38 and 41) is, therefore, largely identical. The marked similarity of the correlation coefficients in these two tables indicates that a separate consideration of the larger-category grouping was of little utility.

Relatively few correlations based upon the broader grouping in Table 41 were of statistically significant size of .20 or above. Only three were of substantial size, ranging from .30 to .34: absent-mindedness among boys and seclusiveness and inefficiency in work, play, etc., among girls, the corresponding coefficients for the other sex being of moderate size, ranging from .19 to .26. Three notations showed moderate correlations in the .20's for both sexes: poor work in school, distractibility, and question of hypophrenia. Three behavior traits among boys showed moderate correlations in the .20's, with low positive coefficients below .20 for girls: laziness, queer behavior, and speech defect (other than stuttering). Four notations among girls showed moderate correlations in the .20's, with low positive coefficients below .20 for boys: repressed manner, preference for younger children as playmates, feeble-minded sibling, and retardation in school.

Two significant negative correlations were found, both among girls,  $-.29 \pm .04$  for "spoiled child" and  $-.22 \pm .05$  for overinterest in sex matters, the corresponding coefficients for boys being negligible.

Among the six sex notations the only correlation of statistically significant size was the negative one of  $-.22 \pm .05$  among girls for overinterest in sex matters. In general, it may be noted that sex problems tended to be negatively or negligibly correlated with all three notations—slow or dull manner, listlessness, and lack of initiative or ambition.

Among the seven physical or psychophysical notations only one meaningful correlation was found—the moderate one of  $.21 \pm .03$  with speech defect (other than stuttering) among boys. In general, it may be concluded that these physical conditions tended to show a low positive correlation with the three notations discussed in this chapter.

Among our four home or familial conditions there were no correlations of material size, all thirty-two coefficients presented in this chapter falling between  $-.17$  and  $.14$ .

## CHAPTER XXVII

### OVERSUGGESTIBILITY; DISTRACTIBILITY; PREFERENCE FOR YOUNGER CHILDREN AS PLAYMATES

The three personality traits oversuggestibility, distractibility, and preference for younger children as playmates may be conveniently considered together in this chapter as frequently noted concomitants of mental deficiency. (In the data of this volume this relation for distractibility is obscured by the fact that our 2,113 boys and 1,181 girls do not include the very young children below 6 years of age and below 50 in intelligence quotient, among whom distractibility is especially frequent.) That these three traits are not similar is shown by the non-significance of their intercorrelations, which range from  $-.06$  to  $.20$ .

The notation oversuggestibility ("patient too easily influenced by others") was found among 354 boys, or 16.8 per cent, and among 174 girls, or 14.7 per cent, and was one of the more frequent behavior notations among our clinic cases. It appeared to be of negligible importance from a personality standpoint, probably of moderate importance from the standpoint of conduct deviation, but of substantial importance as an indicator of "juvenile delinquency," especially among girls, for whom one notes the high tetrachoric correlation of  $.57 \pm .03$  with police arrest (Table 42).

Among both sexes the highest correlation was with bad companions, the coefficients being  $.43 \pm .03$  and  $.40 \pm .04$  for boys and girls respectively. Stealing among boys also showed the substantial correlation of  $.38 \pm .02$  with a corresponding low coefficient of  $.13$  among girls. Running with a gang (calculated for boys only) also showed the substantial correlation of  $.31 \pm .03$ . Sex delinquency (coitus) among girls showed the substantial correlation of  $.38 \pm .04$ , with a corresponding low coefficient of  $.11$  among boys. Loitering or wandering among girls showed the similarly substantial correlation of  $.32 \pm .06$ , with a corresponding moderate

Fantastical lying, .19 and .13; Teasing other children, .19 (boys); Truancy from home, .19 and .17; Overinterest in opposite sex, .18 (girls); Masturbation, .16 and .11; Retardation in school, .16 and .04; Irregular attendance at school, .16 and -.09; Brother in penal detention, .16 and .06; Disturbing influence in school, .15 and .04; Refusal to attend school, .15 and -.07; Exclusion from school, .15 and .14; Question of hypophrenia, .14 and .02; In-correctible, .13 and .09; Swearing (general), .13 (boys); Lack of initiative, .13 and .17; Restless, .13 and .17; Poor work in school, .13 and .06; Grouped: disobedient, etc., .13 and .16; Enuresis, .12 and -.03; Leading others into bad conduct, .12 and .05; Smoking, .12 (boys); Grouped: dull, slow, etc., .12 and .15; Grouped: swearing, etc., .12 and .07; Boastful, "show-off," .11 and .15; Destructive, .11 and .07; Changeable moods, .11 and .07; Slow, dull, .11 and .10; Grouped: "nervous," etc., .11 and .10; Object of teasing, .10 and -.04; Restless in sleep, .10 and .05; Spoiled child, .10 and .03; Stubborn, .09 and .02; Speech defect, .09 and .16; Victim of sex abuse, .09 (girls); Fighting, .08 and .03; Inefficient in work, play, etc., .08 and .13; Irresponsible, .08 and .18; Temper display, .08 and -.02; Bashful, .08 and .00; Complaining of bad treatment by other children, .08 (boys); Lack of interest in school, .07 and .08; Slovenly, .07 and .18; Irregular sleep habits, .07 and .14; Grouped: lack of interest in school, etc., .07 and .04; Repressed, .06 and -.00; Neurological

TABLE 42—Continued

defect, .06 and .04; Sulky, .07 and .11; Overinterest in sex matters, .05 and .17; Crying spells, .05 and .15; Daydreaming, .05 and .08; Listless, .05 and .19; Inferiority feelings, .05 and .09; Emotional instability, .05 and .06; Preference for younger children, .05 and .07; Stuttering, .05 (boys); Former convulsions, .04 and .02; Discord between parents, .04 and .03; Grouped: temper, etc., .04 and -.04; Disobedient, .04 and .08; Nail-biting, .03 and .05; Irritable, .03 and -.08; Grouped: fighting, etc., .03 and .12; Threatening violence, .02 (boys); "Nervous," .02 and .03; Sex denied entirely, .02 and -.04; Grouped: sensitive or worrisome, etc., .02 and .08; Temper tantrums, .01 and .02; Sensitive (general), .01 and .10; Leader, .01 and -.09; Clean, .01 and -.02; Headaches, .01 and -.10; Vicious home conditions, .01 and .11; Inattentive in school, .00 and .02; Hatred or jealousy of sibling, .00 and -.06; Sensitive over specific fact, .00 and .02; Popular, .00 and -.01; Selfish, -.00 and .12; Mental conflict, -.00 and .02; Grouped: depressed, etc., -.00 and .13; Rude, -.01 and -.03; Sullen, -.01 and -.00; Lues, -.01 and .03; Contrary, -.02 and -.11; Depressed, -.02 and .08; Seclusive, -.02 and .17; Lazy, -.03 and .03; Unhappy, -.03 and .12; Attractive manner, -.03 and .06; Finicky food habits, -.04 and .12; Defiant, -.04 and .06; Underweight, -.04 and -.02; Worry over specific fact, -.05 and .15; Quarrelsome, -.06 and .10; Distractible, -.06 and .11; Question of change of personality, -.08 and .16; Question of encephalitis, -.08 and -.14; Feeble-minded sibling, -.08 and -.07; Bossy, -.09 and .11; Immoral home conditions, -.09 and .11; Grouped: egocentric, etc., -.10 and .08; Psychoneurotic, -.13 and .19; Egocentric, -.14 and -.04; Vocational guidance, -.17 and -.08

correlation of  $.20 + .04$  among boys.

Two notations—staying out late at night and staff notation of unfavorable conduct prognosis—showed moderate correlations in the .20's for both sexes. Six behavior traits showed moderate correlations ranging from .20 to .29 among boys but low positive correlations below .20 for girls: "follower," truancy from school, excuse-forming attitude, apprehensiveness, lying, and unpopularity. Three behavior notations among girls similarly showed moderate correlations in the .20's with negligible coefficients ranging from -.09 to .10 among boys: queer behavior, absent-mindedness, and violence.

Among the six sex notations all correlations with one exception were low or negligible, falling below .20. For sex delinquency (coitus) among girls, however, there was a substantial correlation of  $.38 + .04$  with oversuggestibility. Since sex misconduct and the fact of a juvenile-court arrest or commitment among girls are so substantially correlated with the notation oversuggestibility, one wonders to what extent this relation represents the true state of affairs and to what extent it may be due to an overprotective attitude on the part of the parent or friend, who

desired to minimize a patient's conduct troubles by blaming them upon other children. "She is a good girl around home but is too easily influenced by other people."

Among the seven physical or psychophysical notations and among the four home or familial notations there were found no correlation coefficients of significant size.

Distractibility or lack of concentration was noted among 264 boys, or 12.5 per cent, and among 116 girls, or 9.8 per cent. It was especially characteristic of our youngest children.<sup>1</sup>

Among girls its bi-serial correlations with both the personality-total and the conduct-total were fairly high,  $.41 \pm .03$  and  $.44 \pm .03$  respectively, but among boys these coefficients were of only moderate size in the .20's (Table 43). With the police-arrest criterion of importance or "seriousness" its correlations were very negligible.

Its highest correlations among girls were with restlessness,  $.56 \pm .04$ , and with disturbing influence in school,  $.46 \pm .05$ . Among boys the two corresponding correlations were also meaningful,  $.39 \pm .03$  and  $.24 \pm .03$  respectively. Among girls question or diagnosis of encephalitis yielded the very substantial correlation coefficient of  $.44 \pm .07$ , the corresponding coefficient for boys being low,  $.17$ . Two behavior notations among girls each yielded a correlation of  $.40$ —"nervousness" and violence—the corresponding coefficients for boys being  $.26 \pm .03$  and  $.11$ . Among boys the only correlation as large as  $.40 \pm .04$  was with absent-mindedness. Among boys inefficiency in work, play, etc., yielded the substantial correlation of  $.36 \pm .05$ , with a similar correlation among girls of  $.29 \pm .06$ . Among girls two additional notations showed substantial correlations in the .30's, with corresponding moderate correlations in the .20's among boys: poor work in school and bossy manner. There were thirteen notations among girls showing substantial correlations in the .30's but low positive correlations below .20 for boys: question of change of personality, restlessness in sleep, queer behavior, worry over some specific fact, boastful or "show-off" manner, object of teasing by other children, quarrelsomeness, temper tantrums, stubbornness,

## Other Correlations (Positive to Negative)

Contrary, .19 and .00; Overinterest in opposite sex, .19 (girls); Complaining of bad treatment by other children, .18 (boys); Selfish, .17 and .10; Seclusive, .17 and .16; Temper display, .15 and -.03; Irritable, .15 and .19; Leading others into bad conduct, .14 and .18; Swearing (general), .14 (boys); Question of hypophrenia, .14 and .18; Hatred or jealousy of sibling, .13 and .16; Lack of initiative, .13 and .04; Speech defect, .13 and .19; Slowly, .12 and .16; Sulky, .12 and .14; Follower, .12 and .16; Headaches, .12 and .18; Discord between parents, .12 and -.10; Masturbation, .11 and .14; Finicky food habits, .10 and .13; Threatening violence, .10 (boys); Irregular attendance at school, .10 and -.13; Enuresis, .09 and .18; Smoking, .09 (boys); Underweight, .09 and .06; Grouped: sensitive or worrisome, etc., .09 and .16; Nail-biting, .08 and .19; Sensitive over specific fact, .08 and .05; Stuttering, .08 (boys); Refusal to attend school, .07 and .08; Bashful, .07 and -.04; Former convulsions, .07 and .01; Attractive manner, .07 and .08; Rude, .06 and .11; Gang, .06 (boys); Retardation in school, .05 and .14; Leader, .05 and .12; Victim of sex abuse, .05 (girls); Feeble-minded sibling, .03 and .01; Bad companions, .03 and .09; Sensitive (general), .01 and .14; Staying out late at night, -.01 and .12; Unhappy, -.02 and .12; Sex denied entirely, -.02 and .07; Popular, -.02 and .18; Truancy from school, -.03 and .07; Immoral home conditions, -.03 and .09; Sex delinquency (coitus), -.04 and .05; Lues, -.04 and .17; Brother in penal detention, -.04 and -.14; Mental conflict, -.05 and .09; Clean, -.05 and .09; Oversuggestible, -.06 and .11; Repressed, -.07 and .05; Apprehensive, -.08 and .18; Vocational guidance, -.08 and .00; Psychoneurotic, -.14 and .12

destructiveness, distractibility, inattentiveness in school, and exclusion from school.

Five personality difficulties showing moderate correlations in the .20's among both sexes with distractibility were slow or dull manner, listlessness, irresponsibility, "spoiled child," and unpopularity and also the notation teasing other children, which was computed for boys only. Three behavior notations among boys also showed moderate correlations in the .20's but low positive correlations below .20 for the girls: daydreaming, laziness, and loitering or wandering. A large group of twenty-one notations showed moderate correlations in the .20's among girls but low correlations ranging from -.05 to .19 among boys: changeable moods and attitudes, emotional instability, crying spells, irregular sleep habits, inferiority feelings, excuse-forming attitude, ego-centricity, sullenness, incurability, disobedience, defiant attitude, fighting, swearing or bad language (undifferentiated), lying, fantastical lying, stealing, truancy from home, preference for younger children as playmates, overinterest in sex matters, staff notation of unfavorable conduct prognosis, and neurological defect (unspecified).

One notation showed a negative correlation of moderate size among girls, vicious home conditions,  $-.21 \pm .07$ , with a negligible coefficient of .07 among boys.

Among the six sex notations distractibility showed only one coefficient of moderate size— $.23 \pm .06$  for overinterest in sex matters among girls, the boys' coefficient of .06 being negligible.

Among the seven physical or psychophysical notations there were two correlations of statistical significance, both for girls, the very substantial one of  $.44 \pm .07$  for question or diagnosis of encephalitis and  $.29 \pm .05$  with neurological defect (unspecified), the corresponding coefficients for boys being .17 and .18 respectively.

Among the four home or familial correlations there was only one of significant size, the negative coefficient of  $-.21 \pm .07$  for vicious home conditions among girls.

Preference for younger children as playmates in our data appeared to be of little importance, since its correlations with our three criteria of "seriousness" were low, ranging from -.14 to

.15 (Table 44). It was noted among only 7 or 8 per cent of the children discussed in this volume.

The three highest correlations, ranging from .32 to .36, were among girls, the corresponding coefficients among boys being low, falling between .13 and .18: "nervousness" or restlessness

Neurological defect, .19 and .10; Question of encephalitis, .19 and .19; Daydreaming, .18 and .03; Bashful, .18 and .08; Lack of interest in school, .18 and .17; Irresponsible, .17 and .07; Lack of initiative, .17 and .10; Fantastical lying, .16 and .10; Inefficient in work, play, etc., .15 and .18; Temper tantrums, .15 and .15; Seclusive, .15 and -.04; Grouped: disobedient, etc., .15 and .09; Disobedient, .13 and .01; "Nervous," .13 and .19; Repressed, .12 and .00; Apprehensive, .12 and .04; Sulky, .12 and .08; Quarrelsome, .11 and .12; Slovenly, .11 and .06; Stubborn, .11 and -.04; Threatening violence, .11 (boys); Grouped: fighting, etc., .11 and .16; Crying spells, .10 and .16; Violence, .10 and .13; Question of change of personality, .09 and .14; Irritable, .09 and .19; Queer, .09 and -.09; Sensitive (general), .09 and .12; Follower, .08 and .09; Inferiority feelings, .08 and .05; Egocentric, .08 and .15; Sex delinquency (coitus), .08 and -.13; Stealing, .08 and .18; Leading others into bad conduct, .08 and -.11; Boastful, "show-off," .08 and -.06; Lying, .07 and .16; Teasing other children, .07 (boys); Masturbation, .07 and .16; Unhappy, .07 and -.01; Leader, .07 and .06; Grouped: depressed, etc., .06 and .05; Spoiled child, .06 and .08; Finicky food habits, .05 and .04; Depressed, .05 and -.05; Oversuggestible, .05 and .07; Stuttering, .05 (boys); Irregular attendance at school, .05 and .01; Grouped: swearing, etc., .04 and .12; Vicious home conditions, .04 and -.03; Headaches, .04 and .17; Irregular sleep habits, .04 and -.08; Disturbing influence in school, .04 and .16; Loitering, .03 and -.00; Grouped: egocentric, etc., .03 and .16; Bad companions, .02 and .12; Swearing (general), .01 (boys); Psychoneurotic, .01 and -.08; Conduct prognosis bad, .01 and .14; Complaining of bad treatment by other children, .01 (boys); Overinterest in opposite sex, .01 (girls); Truancy from home, .00 and -.01; Hatred or jealousy of sibling, -.00 and .01; Excuse-forming, -.01 and .02; Truancy from school, -.01 and .11; Rude, -.01 and .00; Refusal to attend school, -.01 and .07; Vocational guidance, -.03 and .07; Staying out late at night, -.03 and -.04; Smoking, -.04 (boys); Temper display, -.04 and .18; Popular, -.04 and -.06; Clean, -.04 and .07; Attractive manner, -.04 and .09; Incorrigible, -.05 and .14; Immoral home conditions, -.06 and -.13; Sex denied entirely, -.06 and .06; Sul- len, -.06 and .10; Emotional instability, -.07 and .06; Lies, -.07 and -.15; Dis- cord between parents, -.07 and -.06; Victim of sex abuse, -.08 (girls); Defiant, -.09 and .11; Underweight, -.09 and .13; Gang, -.12 (boys); Brother in penal de- tention, -.14 and -.03

(including irritable temperament and changeable moods or attitudes, undifferentiated), mental conflict, and question of hypophrenia.

Three notations showed moderate correlations in the .20's for both sexes: restlessness in sleep, object of teasing by other children, and poor work in school. Three additional notations

yielded moderate correlations in the .20's for boys but low correlations below .20 for girls: selfishness, overinterest in sex matters, and speech defect (other than stuttering). A large list of eighteen miscellaneous problems among girls yielded moderate correlations in the .20's, with low corresponding coefficients ranging from  $-.03$  to  $.19$  among boys: inattentiveness in school, restlessness, absent-mindedness, slow or dull manner, distractibility, listlessness, laziness, changeable moods or attitudes, bossy manner, fighting, destructiveness, unpopularity, temper tantrums or display (undifferentiated), sensitiveness over specific fact, enuresis, nail-biting, retardation in school, and exclusion from school. Worry over some specific fact, curiously, yielded a moderate positive correlation of  $.22 \pm .09$  among girls and a significant negative coefficient of  $-.24 \pm .06$  among boys.

In addition to worry over some specific fact there were three negative coefficients of statistically significant size with preference for younger children as playmates: among boys  $-.27 \pm .05$  for feeble-minded sibling, and among girls  $-.25 \pm .08$  and  $-.20 \pm .04$  for contrariness and former convulsions respectively.

Among the six sex notations the only considerable correlation with preference for younger children as playmates was for overinterest in sex matters among boys,  $.24 \pm .06$ , with the corresponding coefficient for girls of  $.15$ .

Among our seven physical or psychophysical notations there were two coefficients of unquestionably significant size,  $.23 \pm .05$  for enuresis among girls and  $.22 \pm .05$  for speech defect (other than stuttering) among boys. The correlation of  $.19$  among both boys and girls for question or diagnosis of encephalitis is also suggestive but because of the paucity of cases was scarcely of statistical significance.

None of the four home or familial conditions showed meaningful correlations with preference for younger children as playmates, the coefficients ranging from  $-.14$  to  $.04$ .

## CHAPTER XXVIII

### "NERVOUSNESS"; RESTLESSNESS; IRRITABILITY

The three personality problems—"nervousness," restlessness, and irritable temperament—were among the most frequent of behavior traits noted in our case material. Occasionally they appeared to be the chief reason for the child's being referred to the clinic of the Illinois Institute for Juvenile Research, but more commonly they were elicited in the actual interview by the psychiatric social worker with the parent, teacher, or other informant. Collectively they are of moderate to substantial importance clinically but of little moment as indicators of "juvenile delinquency." Their very substantial intercorrelations, ranging from .26 to .51, indicate their essential similarity.

"Nervousness" in our data was a poorly defined term of vague meaning, hence our persistent use of quotation marks whenever it is mentioned in this study. It showed substantial bi-serial correlations in the .30's with personality-total among both sexes and moderate correlations of  $.19 \pm .02$  and  $.24 \pm .04$  with the conduct-total for boys and girls respectively (Table 45). With the police-arrest criterion the correlation for both sexes was zero. "Nervousness" was noted among 344, or 16.3 per cent, of our 2,113 White boys and 197, or 16.7 per cent, of our 1,181 White girls.

The highest correlations among both sexes were with restlessness,  $.42 \pm .03$  and  $.51 \pm .03$  among boys and girls respectively. Among girls there were in addition three very substantial correlations ranging from .40 to .47, with substantial correlations among boys ranging from .30 to .34: changeable moods or attitudes, restlessness in sleep, and neurological defect (unspecified). Question or diagnosis of encephalitis and distractibility similarly yielded fairly high correlations in the .40's among girls but lesser coefficients of  $.14$  and  $.26 \pm .03$  respectively among boys.

Four behavior notations yielded substantial correlations in the .30's for both sexes: psychoneurotic trends, queer behavior,

## Other Correlations (Positive to Negative)

Masturbation, .19 and .19; Underweight, .19 and .13; Contrary, .18 and .17; Temper display, .18 and .03; Swearing (general), .18 (boys); Boastful, "show-off," .16 and .15; Stubborn, .16 and .13; Rude, .15 and .05; Mental conflict, .15 and .13; Clean, .15 and .01; Selfish, .14 and .12; Leader, .14 and .12; Preference for younger children, .13 and .19; Grouped: disobedient, etc., .13 and .17; Disobedient, .12 and .19; Lack of interest in school, .12 and .12; Seclusive, .12 and .05; Conduct prognosis bad, .12 and -.01; Stuttering, .12 (boys); Grouped: lack of interest in school, etc., .12 and .15; Enuresis, .11 and .19; Bashful, .11 and .10; Speech defect, .11 and .17; Grouped: swearing, etc., .11 and .07; Inefficient in work, play, etc., .10 and .18; Sulky, .10 and -.04; Unhappy, .10 and .18; Excuse-forming, .09 and .05; Listless, .09 and -.04; Smoking, .08 (girls); Incorrigible, .07 and .14; Grouped: egocentric, etc., .07 and .14; Inattentive in school, .06 and .19; Irresponsible, .06 and .14; Lying, .06 and .19; Egocentric, .06 and .15; Bad companions, .06 and -.02; Refusal to attend school, .05 and -.10; Poor work in school, .05 and .14; Overinterest in sex matters, .04 and .07; Follower, .04 and .02; Loitering, .03 and -.04; Sullen, .03 and .04; Lack of initiative, .03 and -.05; Attractive manner, .03 and .07; Leading others into bad conduct, .02 and .10; Stealing, .02 and .07; Oversuggestible, .02 and .03; Question of hypophrenia, .02 and .01; Popular, .02 and .06; Victim of sex abuse, .02 (girls); Gang, .01 (boys); Truancy from school, .01 and .04; Repressed, .01 and .15; Vicious home conditions, .00 and -.15; Discord between parents, -.00 and -.11; Defiant, -.01 and .15; Slowly, -.01 and .00; Grouped: -dull, slow, etc., -.01 and -.02; Threatening violence, -.01 (boys); Overinterest in opposite sex, -.01 (girls); Lazy, -.02 and -.01; Truancy from home, -.02 and .12; Sex denied entirely, -.02 and .14; Irregular attendance at school, -.02 and -.08; Staying out late at night, -.03 and .06; Slow, dull, -.03 and -.01; Lues, -.04 and .04; Retardation in school, -.07 and -.14; Immoral home conditions, -.14 and .12

Omitted—Grouped: "nervous," etc.

irritable temperament, and temper tantrums or display (undifferentiated). Six behavior notations yielded substantial correlations in the .30's among girls and moderate coefficients in the .20's for boys: crying spells, apprehensiveness, question of change of per-

sonality, "spoiled child," absent-mindedness, and finicky food habits. Four behavior difficulties among girls similarly yielded substantial correlations in the .30's but low positive correlations below .20 for boys: temper tantrums, fighting, disturbing influence in school, and inferiority feelings.

Six personality and conduct problems showed moderate correlations in the .20's among both sexes: emotional instability, irregular sleep habits, nail-biting, bossy manner, sensitiveness in general, daydreaming; and also two which were calculated for boys only, teasing other children and complaining of bad treatment by other children. Among boys there were five behavior notations showing moderate correlations in the .20's but low positive correlations below .20 for girls: worry over some specific fact, depressed spells, unpopularity, object of teasing by other children, and fantastical lying. Among girls there were eight notations showing moderate coefficients in the .20's, the corresponding correlations for the boys ranging from .08 to .19: violence, destructiveness, quarrelsomeness, exclusion from school, sensitiveness over some specific fact, hatred or jealousy of sibling, headaches, and former convulsions.

There were several negative coefficients of significant magnitude with "nervousness." Brother in penal detention yielded tetrachoric correlations of  $-.20 \pm .04$  and  $-.30 \pm .05$  among boys and girls respectively. Among boys feeble-minded sibling yielded the correlation of  $-.28 \pm .04$ . Among girls sex delinquency (coitus) and the notation "request for vocational guidance" showed negative correlations of moderate size in the  $-.20$ 's.

Among sex notations we have noted the significant negative correlation of  $-.24 \pm .04$  for sex delinquency (coitus) among girls, the corresponding boys' coefficient being negligible. Among both sexes masturbation showed a correlation of .19, which, though suggestive, is not of marked significance. The other sex notations—overinterest in sex matters, sex misbehavior denied entirely, and (calculated for girls only) overinterest in opposite sex and victim of sex abuse—showed negligible correlations with "nervousness."

Among the physical or psychophysical notations neurological defect (unspecified) showed the meaningful coefficients of  $.31 \pm .04$  and  $.44 \pm .04$  among boys and girls respectively. Question or

diagnosis of encephalitis among girls similarly yielded the fairly high correlation of  $.40 \pm .06$ , with a corresponding low correlation among boys of  $.14$ . Among the other five notations in this field—underweight condition, enuresis, lues, speech defect, and stuttering—the coefficients were low, ranging from  $-.04$  to  $.19$ .

Brother in penal detention, as we have noted, showed the curious negative correlations of  $-.20 \pm .04$  and  $-.30 \pm .05$  among boys and girls respectively. The other three notations concerning home or familial conditions—discord between parents and vicious or immoral home conditions—showed low correlations ranging from  $-.15$  to  $.12$ .

Restlessness, overactivity, hyperkinesis, "patient has too much energy," showed moderate to substantial correlations ranging from  $.25$  to  $.43$  with the personality-total and the conduct-total but negligible relations with police arrest. It was noted among 559, or 26.5 per cent, of our boys and among 258, or 21.8 per cent, of our girls and is one of the most frequently noted behavior problems among our children. Its highest correlations among both sexes were for "nervousness" and distractibility, with coefficients among girls of  $.51 \pm .03$  and  $.56 \pm .04$  respectively and among boys of  $.43 \pm .03$  and  $.39 \pm .03$  respectively (Table 46). Changeable moods,

## Other Correlations (Positive to Negative)

Spoiled child, .19 and .19; Loitering, .18 and .14; Threatening violence, .18 (boys); Irregular sleep habits, .18 and .19; Irresponsible, .17 and .16; Swearing (general), .17 (boys); Overinterest in opposite sex, .17 (girls); Stealing, .15 and .19; Sulky, .15 and .14; Smoking, .14 (boys); Temper display, .14 and .13; Victim of sex abuse, .14 (girls); Staying out late at night, .13 and .15; Listless, .13 and .17; Oversuggestible, .13 and .17; Follower, .13 and .13; Overinterest in sex matters, .12 and .18; Sensitive (general), .11 and .13; Sensitive over specific fact, .11 and .09; Poor work in school, .11 and .14; Underweight, .11 and .10; Bad companions, .10 and .17; Former convulsions, .10 and .11; Refusal to attend school, .09 and .02; Truancy from school, .06 and .17; Lazy, .08 and .08; Gang, .08 (boys); Seclusive, .08 and .17; Discord between parents, .08 and -.05; Complaining of bad treatment by other children, .07 (boys); Lack of initiative, .06 and .01; Attractive manner, .06 and .05; Popular, .05 and .03; Clean, .05 and .03; Irregular attendance at school, .05 and -.12; Speech defect, .05 and .15; Vocational guidance, .04 and .02; Slow, dull, .03 and .11; Sex denied entirely, .01 and .09; Apprehensive, -.00 and .14; Grouped: dull, slow, etc., -.00 and .11; Repressed, -.04 and -.00; Stuttering, -.04 (boys); Bashful, -.05 and -.05; Question of hypophrenia, -.05 and .05; Immoral home conditions, -.08 and -.01; Vicious home conditions, -.08 and -.10; Retardation in school, -.08 and -.02; Sex delinquency (coitus), -.09 and .09; Lues, -.10 and -.03; Brother in penal detention, -.11 and .18; Feeble-minded sibling, -.11 and -.13

Omitted—Grouped: "nervous," etc.

emotional instability, and question or diagnosis of encephalitis among girls yielded very substantial correlations in the .40's, and moderate coefficients ranging from .21 to .30 among boys. Among girls fighting and violence also yielded the fairly substantial correlations of .44 ± .03 and .45 ± .04 respectively, the boys' coefficients being low, .15 for each trait.

Disturbing influence in school and rudeness among boys yielded substantial correlations in the .30's and moderate coefficients in the .20's among girls. Five behavior traits among girls showed substantial correlations in the .30's with corresponding moderate coefficients in the .20's for boys: restlessness in sleep,

irritable temperament, boastful or "show-off" manner, inattentiveness in school, and incorrigibility. Seven additional notations yielded substantial correlations in the .30's for girls but low positive coefficients below .20 for boys: temper tantrums, quarrelsomeness, crying spells, unpopularity, excuse-forming attitude, lack of interest in school, and exclusion from school.

Restlessness showed moderate correlations in the .20's for both sexes with the following eleven notations: nail-biting, ficky food habits, disobedience, destructiveness, staff notation of unfavorable conduct prognosis, question of change of personality, depressed spells, fantastical lying, bossy manner, "leader," neurological defect (unspecified); and also two which were calculated for boys only, teasing other children and swearing or bad language (undifferentiated). Six behavior traits among boys showed moderate correlations in the .20's but low positive coefficients below .20 for girls: absent-mindedness, slovenliness, inefficiency in work, play, etc., unhappiness, selfishness, and contrariness. A large list of twenty behavior and other notations showed moderate correlations in the .20's for girls but low coefficients ranging from -.03 to .18 for boys: sensitiveness or worrisomeness (undifferentiated), worry over some specific fact, inferiority feelings, mental conflict, psychoneurotic trends, queer behavior, hatred or jealousy of sibling, egocentricity, defiant attitude, stubbornness, leading others into bad conduct, truancy from home, sullenness, lying, daydreaming, object of teasing by other children, preference for younger children as playmates, masturbation, headaches, and enuresis.

Among the six sex notations restlessness showed only one coefficient of significant size,  $.21 \pm .04$  for masturbation among girls.

Among the seven physical or psychophysical notations there were several meaningful correlations. Question or diagnosis of encephalitis showed tetrachoric  $r$ 's of  $.27 \pm .05$  and  $.45 \pm .06$  for boys and girls respectively. Neurological defect (unspecified) showed the respective moderate coefficients of  $.20 \pm .03$  and  $.28 \pm .04$ . Among girls enuresis showed a correlation of  $.21 \pm .04$ , the corresponding boys' coefficient being negligible, .07.

Among the four home or familial notations all correlations were low, ranging from -.11 to .18.

Irritable temperament, "patient high-strung or impatient" was noted among 448, or 21.2 per cent, of our boys and among 175, or 14.8 per cent, of our girls. Its bi-serial correlations with our criteria of personality and conduct deviation generally were of moderate size, ranging from .27 to .30. With the police-arrest criterion the girls' correlation was  $.22 \pm .04$ , but among boys the correlation was negligible,  $.04 \pm .03$  (Table 47).

Irresponsible, .19 and .16; Sulky, .19 and .19; Depressed, .18 and .19; Absent-minded, .18 and .06; Excuse-forming, .17 and .10; Worry over specific fact, .17 and .17; Conduct prognosis bad, .17 and -.04; Grouped: sensitive or worrisome, etc., .16 and .13; Seclusive, .16 and .11; Bashful, .16 and .08; Lying, .16 and .11; Disturbing influence in school, .16 and .19; Destructive, .16 and .10; Teasing other children, .15 (boys); Listless, .15 and -.11; Distractible, .15 and .19; Refusal to attend school, .14 and .09; Inefficient in work, play, etc., .13 and .18; Lack of interest in school, .13 and .14; Overinterest in sex matters, .13 and .10; Lack of initiative, .13 and -.12; Mental conflict, .13 and .06; Complaining of bad treatment by other children, .13 (boys); Former convulsions, .13 and .07; Speech defect, .12 and -.04; Nail-biting, .12 and .16; Lazy, .11 and .11; Masturbation, .11 and -.01; Apprehensive, .11 and -.02; Overinterest in opposite sex, .11 (girls); Lues, .10 and -.05; Exclusion from school, .10 and .04; Truancy from home, .10 and -.11; Stealing, .10 and .01; Gang, .09 (boys); Slovenly, .09 and -.01; Preference for younger children, .09 and .19; Poor work in school, .09 and .06; Follower, .09 and -.00; Clean, .09 and .07; Loitering, .07 and .06; Sensitive over specific fact, .07 and .02; Popular, .07 and .13; Unhappy, .06 and .14; Object of teasing, .06 and .15; Truancy from school, .06 and .08; Leading others into bad conduct, .06 and .13; Discord between parents, .04 and .11; Bad companions, .03 and -.03; Oversuggest-

TABLE 47—Continued

ible, .03 and -.08; Stuttering, .03 (boys); Grouped: dull, slow, etc., .02 and -.04; Underweight, .02 and .17; Staying out late at night, .00 and .11; Inattentive in school, -.00 and .18; Vocational guidance, -.02 and .00; Attractive manner, -.04 and .02; Question of hypophrenia, -.04 and -.04; Slow, dull, -.05 and -.01; Irregular attendance at school, -.06 and .04; Repressed, -.07 and .06; Retardation in school, -.11 and -.11; Feeble-minded sibling, -.14 and -.08; Sex denied entirely, -.17 and .03

Omitted—Grouped: "nervous," etc.; Grouped: temper, etc.

Its highest correlations, ranging from .30 to .44 among both sexes, were for "nervousness," fighting or quarrelsomeness (undifferentiated), violence, threatening violence (calculated for boys only), temper tantrums, changeable moods or attitudes, crying spells, temper display, and question or diagnosis of encephalitis. Question of change of personality among boys also yielded the substantial correlation of .33 + .04 and among girls the moderate correlation of .26 + .06. Among girls there were nine behavior difficulties yielding similar substantial correlations, ranging from .30 to .42, with corresponding moderate coefficients in the .20's for boys: restlessness, restlessness in sleep, disobedience or incorrigibility (undifferentiated), contrariness, fighting, quarrelsomeness, rudeness, selfishness, and finicky food habits. Incorrigibility and "leader" also yielded substantial correlations in the .30's for girls but low coefficients below .20 for boys.

Eight behavior problems showed moderate correlations in the .20's among both sexes: emotional instability, irregular sleep habits, bossy manner, hatred or jealousy of sibling, sullenness, swearing or bad language (undifferentiated), "spoiled child," and fantastical lying and also smoking (calculated for boys only). Four others showed moderate correlations in the .20's for boys but low positive coefficients below .20 for girls: stubbornness, queer behavior, psychoneurotic trends, and unpopularity. Among girls there were twelve additional notations with moderate correlations in the .20's but low positive correlations below .20 for boys: boastful or "show-off" manner, disobedience, defiant attitude, egocentricity, sensitiveness in general, inferiority feelings, day-dreaming, depressed spells or unhappiness (undifferentiated), lack of interest or inattentiveness in school studies or employment (undifferentiated), enuresis, headaches, and neurological defect (unspecified).

There were five significant negative correlations with irritable temperament, ranging from  $-.20$  to  $-.26$ , all among girls: sex delinquency (coitus), victim of sex abuse by older child or person (calculated for girls only), immoral and vicious home conditions, and brother in penal detention.

Among the sex notations there were two coefficients of significant size, both of negative sign, sex delinquency (coitus) among girls,  $-.24 \pm .04$ , and victim of sex abuse by older child or person (calculated for girls only),  $-.20 \pm .05$ .

Among physical or psychophysical notations there were several correlations of significant size. Question or diagnosis of encephalitis yielded the substantial correlations of  $.30 \pm .05$  and  $.31 \pm .07$  for boys and girls respectively. Neurological defect (unspecified) and enuresis among girls showed moderate correlations in the .20's.

Among home or familial conditions irritable temperament showed three correlations of moderate size in the .20's, all negative in sign and all among girls: vicious and immoral home conditions and brother in penal detention.

When the three personality problems, "nervousness," restlessness, and irritable temperament, together with changeable moods or attitudes (Table 35, p. 231), are combined under one rubric, we have the correlation coefficients shown in Table 48. Under this

Former convulsions, .18 and .09; Mental conflict, .17 and .19; Follower, .16 and .09; Lack of initiative, .16 and .00; Smoking, .16 (boys); Irresponsible, .16 and .19; Overinterest in opposite sex, .15 (girls); Unhappy, .14 and .16; Overinterest in sex matters, .13 and .17; Poor work in school, .12 and .11; Lazy, .12 and .09; Loitering, .11 and .11; Oversuggestible, .11 and .10; Clean, .10 and .08; Refusal to attend school, .10 and -.03; Underweight, .10 and .18; Gang, .09 (boys); Truancy from school, .09 and .10; Bashful, .09 and .08; Discord between parents, .08 and .02; Truancy from home, .08 and .11; Stuttering, .08 (boys); Bad companions, .07 and .09; Staying out late at night, .05 and .05; Grouped: dull, slow, etc., .04 and .01; Popular, .04 and .07; Attractive manner, .02 and .08; Repressed, .01 and .09; Lues, -.03 and -.03; Irregular attendance at school, -.03 and -.17; Slow, dull, -.03 and -.03; Question of hypophrenia, -.04 and .04; Vicious home conditions, -.05 and -.12; Victim of sex abuse, -.05 (girls); Sex denied entirely, -.08 and .14; Retardation in school, -.11 and -.16; Immoral home conditions, -.15 and -.10

Omitted—Changeable moods; Irritable; Restless; "Nervous"

broader grouping fall 987, or 46.7 per cent, of our boys and 488, or 41.3 per cent, of our girls. Almost a half of our clinic population thus manifests one or more of these personality problems.

This combined "broader grouping" showed very substantial correlations ranging from .35 to .48 with personality-total and conduct-total but only a minor relation to the police-arrest criterion of overt juvenile delinquency, unless one considers the negative tetrachoric correlation of  $-.20 + .04$  among girls as meaningful.

Three personality notations—distractibility, restlessness in sleep, and temper tantrums—among girls yielded high correlations in the .50's, with substantial correlations among boys in the .30's. Fighting among girls also yielded a high correlation of  $.56 + .04$ , with a moderate coefficient among boys of  $.24 + .03$ . Four notations among girls yielded very substantial correlations in the .40's and substantial coefficients in the .30's for boys: question or diagnosis of encephalitis, violence, crying spells, and finicky food habits. Three additional notations among girls yielded very substantial correlations in the .40's, with corresponding moderate coefficients in the .20's among boys: quarrelsomeness, inattentiveness in school, and neurological defect (unspecified). Among both sexes substantial correlations in the .30's were found for emotional instability and disobedience or incorrigibility (undifferentiated). Rudeness and contrariness among boys also yielded substantial correlations in the .30's, with corresponding moderate correlations in the .20's among girls. Seventeen behavior difficulties among girls yielded substantial correlations in the .30's, with moderate coefficients in the .20's among boys: question of change of personality, psychoneurotic trends, "spoiled child," queer behavior, irregular sleep habits, sensitiveness in general, unpopularity, bossy manner, stubbornness, incorrigibility, destructiveness, temper display, disturbing influence in school, selfishness, sulkiness, boastful or "show-off" manner, and nail-biting. Six additional notations among girls also showed substantial correlations in the .30's but low positive correlations below .20 for boys: defiant attitude, fantastical lying, exclusion from school, object of teasing by other children, preference for younger children as playmates, and enuresis.

Ten miscellaneous notations showed moderate correlations in the .20's among both sexes with the larger grouping "nervousness" or restlessness (undifferentiated): daydreaming, depressed spells, absent-mindedness, worry over some specific fact, egocentricity, hatred or jealousy of sibling, disobedience, swearing or

bad language (undifferentiated), masturbation, headaches; and the following three notations which were calculated for boys only: threatening violence, teasing other children, and complaining of bad treatment by other children. Four notations among boys showed moderate correlations in the .20's, with low positive coefficients below .20 among girls: listlessness, slovenliness, lack of interest in school, and staff notation of unfavorable conduct prognosis. Among girls there were twelve behavior traits showing moderate correlations in the .20's, with low positive coefficients below .20 for the boys: apprehensiveness, inferiority feelings, sensitivity over some specific fact, seclusiveness, sullenness, inefficiency in work, play, etc., excuse-forming attitude, stealing, lying, leading others into bad conduct, "leader," and speech defect.

There were four negative coefficients of moderate size in the -.20's: among boys for feeble-minded sibling, and among girls for sex delinquency (coitus), brother in penal detention, and "request for vocational guidance."

Regarding the sex notations, the physical and psychophysical notations, and the home and familial notations, we may summarize the data of Tables 45, 46, 47, 48, and Table 35 (changeable moods or attitudes) considered in this chapter as follows. Among girls sex delinquency (coitus) showed moderate negative correlations in the .20's with "nervousness" and irritable temperament, the boys' correlations being negligible. Masturbation among both sexes showed moderate or low positive correlations with "nervousness," restlessness, and changeable moods or attitudes. The remaining four sex notations showed only occasional moderate correlations in this field.

Question or diagnosis of encephalitis and neurological defect (unspecified) consistently showed substantial correlations, several of which were in the .40's, with all five notations "nervousness," restlessness, irritable temperament, changeable moods or attitudes, and the broader grouping of "nervousness" or restlessness (undifferentiated). Enuresis among girls showed moderate correlations ranging from .19 to .27 with "nervousness," restlessness, and irritable temperament, the corresponding coefficients among boys, ranging from .05 to .11, being low and positive. Speech defect (other than stuttering) among girls showed the moderate tetrachoric  $r$  of  $.22 \pm .04$  with the combined grouping "nervousness."

or restlessness (undifferentiated) as shown in Table 48, but all other correlations were below .20. Stuttering, underweight condition, and lues (diagnosed or questioned) showed only low or negligible correlations with all five personality traits discussed in this chapter.

Among the four home or familial notations, brother in penal detention showed generally negative correlations of moderate size ranging from .18 to -.30 among girls for all five notations considered in this chapter. Among girls irritable temperament showed moderate negative correlations of  $-.24 \pm .06$  and  $-.26 \pm .05$  with vicious and immoral home conditions respectively.

In brief, the trends appearing among the correlations discussed in this chapter for the interrelated personality notations "nervousness," restlessness, irritable temperament, together with changeable moods or attitudes (Table 35, p. 231) is summarized in this paragraph. The neuropsychiatric notations, question or diagnosis of encephalitis and neurological defect (unspecified), which in our data overlap to a considerable extent, showed very meaningful correlations. Behavior problems showing substantial to high relationships were distractibility, temper tantrums, and, to a lesser extent, temper display, crying spells or crying easily, fighting (especially among girls), violence, restlessness in sleep, queer behavior, and question of change of personality.

Additional personality and conduct difficulties showing consistent moderate correlations in this field were staff notation of emotional instability, staff notation of psychoneurotic trends, "spoiled child," boastful or "show-off" manner, fantastical lying, bossy manner, rudeness, unpopularity, inferiority feelings or attitudes (especially among girls), depressed moods or spells, sensitiveness in general, quarrelsomeness, disturbing influence in school, finicky food habits, and nail-biting.

Masturbation among both sexes showed several moderate positive correlations, while sex delinquency (coitus) among girls showed several negative correlations of moderate size.

Among girls, brother in penal detention showed moderate negative correlations in the -.20's.

## CHAPTER XXIX

### RESTLESSNESS IN SLEEP AND IRREGULAR SLEEP HABITS

The two notations restlessness in sleep and irregular sleep habits or insomnia could not always be readily distinguished in the case records, but the difference is clear enough. Restlessness in sleep implies tossing, grinding of teeth, crying out, or "nightmares," after the child has fallen asleep, while irregular sleep habits implies wakefulness at a time when children are normally asleep, which may be due to insomnia, to faulty family training in bedtime hours, or to "reversal of sleep" occasionally occurring as a psychiatric symptom. Their intercorrelations were moderate to substantial, the tetrachoric coefficients for boys and girls being  $.28 \pm .04$  and  $.37 \pm .06$  respectively. Both showed moderate to substantial bi-serial  $r$ 's, ranging from  $.23$  to  $.42$  with the personality- and conduct-totals. With the police-arrest criterion of juvenile delinquency the tetrachoric correlations with restlessness in sleep were negligible, while those with irregular sleep habits were of significant size though moderate, the coefficients being  $.24 \pm .04$  among boys and  $.31 \pm .06$  among girls.

Restlessness in sleep was one of the most frequently noted behavior traits in our data, appearing in 324 cases, or 15.3 per cent, of our 2,113 boys and in 146 cases, or 12.4 per cent, of our 1,181 girls.

Its highest correlation ( $.56 \pm .03$ ) was among girls for the broader grouping "nervousness" or restlessness (including irritable temperament and changeable moods or attitudes, undifferentiated), the boys' correlation of  $.34 \pm .03$  also being substantial (Table 49). Among girls two other notations yielded fairly high correlations in the .40's—"nervousness" and nail-biting—with corresponding meaningful coefficients of  $.30 \pm .03$  and  $.27 \pm .03$  among boys. Headaches among boys yielded the fairly high correlation of  $.42 \pm .04$ , the corresponding coefficient among girls being  $.28 \pm .06$ .

Sex delinquency (coitus).....	-.01	-.23 ± .04

## Other Correlations (Positive to Negative)

Boastful, "show-off," .19 and .13; Sulky, .19 and .14; Worry over specific fact, .17 and .12; Stubborn, .15 and .19; Grouped: depressed, etc., .14 and .17; Listless, .14 and .06; Bashful, .14 and .08; Overinterest in sex matters, .14 and .16; Rude, .14 and .14; Inefficient in work, play, etc., .14 and .14; Contrary, .13 and .11; Threatening violence, .13 (boys); Spoiled child, .13 and .17; Follower, .13 and .06; Irregular attendance at school, .13 and -.04; Vicious home conditions, .13 and -.19; Popular, .12 and .03; Stuttering, .12 (boys); Swearing (general), .12 (boys); Leading others into bad conduct, .12 and .05; Object of teasing, .11 and .17; Emotional instability, .11 and -.02; Underweight, .11 and .04; Speech defect, .11 and .14; Complaining of bad treatment by other children, .10 (boys); Oversuggestible, .10 and .05; Egocentric, .09 and .18; Truancy from home, .08 and .16; Bad companions, .07 and .09; Irresponsible, .07 and .11; Gang, .07 (boys); Excuse-forming, .07 and .16; Repressed, .07 and .09; Exclusion from school, .07 and .16; Lues, .07 and -.02; Grouped: dull, slow, etc., .07 and .09; Grouped: lack of interest in school, etc., .07 and .17; Attractive manner, .06 and .03; Seclusive, .06 and .01; Lazy, .06 and .04; Incurable, .06 and -.00; Lack of interest in school, .05 and .08; Slowly, .05 and .14; Sensitive over specific fact, .05 and .14; Poor work in school, .05 and .02; Clean, .05 and .08; Immoral home conditions, .04 and -.07; Question of hypophrenia, .04 and .02; Loitering, .04 and .18; Victim of sex abuse, .04 (girls); Refusal to attend school, .03 and .09; Sullen, .03 and .12; Slow, dull, .03 and .06; Sex denied entirely, .02 and .05; Unhappy, .02 and -.01; Overinterest in opposite sex, .02 (girls); Mental conflict, .01 and .19; Lack of initiative, .00 and .11; Truancy from school, -.00 and .10; Staying out late at night, -.02 and .18; Retardation in school, -.04 and -.11; Conduct prognosis bad, -.06 and .11; Brother in penal detention, -.14 and -.17; Feeble-minded sibling, -.14 and -.15; Vocational guidance, -.17 and -.10

Finicky food habits among both sexes yielded substantial correlations in the .30's. Nine notations among girls yielded substantial correlations with restlessness in sleep in the .30's and moderate coefficients in the .20's among boys: irregular sleep habits, restlessness, changeable moods or attitudes, irritable temperament, temper tantrums or display (undifferentiated), question of change of personality, queer behavior, neurological defect (unspecified), and enuresis. Ten additional notations also yielded substantial correlations in the .30's among girls but low positive coefficients below .20 for boys: distractibility, absent-mindedness, violence, defiant attitude, disturbing influence in school, hatred or jealousy of sibling, unpopularity, fantastical lying, stealing, and question or diagnosis of encephalitis.

Three notations—daydreaming, preference for younger children as playmates, and former convulsions—showed moderate correlations in the .20's for both sexes. Teasing other children and smoking among boys also showed moderate correlations in the .20's, the coefficients for girls not being computed because of the paucity of girls' cases. Three additional notations among boys showed moderate correlations in the .20's but low or negligible coefficients below .20 among girls: psychoneurotic trends, sensitiveness in general, and discord between parents. Eighteen personality and conduct traits among girls also showed moderate correlations in the .20's, the correlations for boys being low and positive (below .20): apprehensiveness, temper tantrums, temper display, fighting, quarrelsomeness, bossy manner, destructiveness, selfishness, lying, swearing or bad language (undifferentiated), disobedience, inattentiveness in school, inferiority feelings, sensitiveness or worrisomeness (undifferentiated), depressed moods or spells, crying spells, masturbation, and "leader."

The only negative correlation of significant size with restlessness in sleep was among girls for sex delinquency (coitus),  $-.23 \pm .04$ , the boys' coefficient being negligible ( $-.01$ ).

Among the six sex notations masturbation among girls yielded a positive correlation of  $.28 \pm .05$  and sex delinquency (coitus) among girls a negative coefficient of  $-.23 \pm .04$ , all other coefficients in this field being low or negligible.

Among the seven physical or psychophysical notations neurological defect (unspecified) showed substantial correlations of

.28  $\pm$  .04 and .32  $\pm$  .05 among boys and girls respectively. Question or diagnosis of encephalitis showed corresponding coefficients of .15 and .36  $\pm$  .07. Enuresis (continuing beyond third birthday) showed moderate to substantial correlations of .26  $\pm$  .03 and .31  $\pm$  .04 for boys and girls respectively. The correlations for underweight condition, lues, speech defect, and stuttering were low or negligible.

Among the four home or familial notations the only correlation of significant size with restlessness in sleep was with discord between parents among boys, .20  $\pm$  .03, all other correlations in this field ranging between -.19 and .13.

Irregular sleep habits or insomnia was noted among 123 boys, or 5.8 per cent, and among 64 girls, or 5.4 per cent.

Its highest correlations were among girls with question or diagnosis of encephalitis, .44  $\pm$  .09, and with queer behavior, .40  $\pm$  .07, the corresponding coefficients for boys being .30  $\pm$  .07 and .16 (Table 50). Question of change of personality and finicky food habits yielded substantial correlations in the .30's for both sexes. Fantastical lying among boys yielded the substantial correlation of .30  $\pm$  .06 but a negligible correlation (-.01) among girls. Three behavior difficulties among girls showed substantial correlations in the .30's, with moderate coefficients in the .20's among boys: restlessness in sleep, "nervousness" or restless (undifferentiated), and swearing or bad language (undifferentiated). Eight additional notations among girls also showed substantial correlations in the .30's, with low or negligible coefficients below .20 among boys: changeable moods or attitudes, emotional instability, sensitiveness in general, crying spells, apprehensiveness, staff notation of psychoneurotic trends (unspecified), irregular attendance at school, and neurological defect (unspecified).

Twelve personality and conduct problems showed moderate correlations with irregular sleep habits in the .20's for both sexes: irritable temperament, "nervousness," temper tantrums, boastful or "show-off" manner, violence, fighting or quarrelsomeness (undifferentiated), disobedience, incorrigibility, staying out late at night, refusal to attend school, "spoiled child," and worry over some specific fact. Four notations (which were not computed for girls because of paucity of cases) also showed moderate

## Other Correlations (Positive to Negative)

Bad companions, .18 and .17; Sullen, .18 and -.07; Lying, .18 and .16; Restless, .18 and .19; Stealing, .17 and .11; Sensitive over specific fact, .17 and .17; Mental conflict, .17 and -.04; Swearing (general), .16 (boys); Headaches, .16 and .16; Discord between parents, .16 and .19; Grouped: depressed, etc., .16 and .15; Contrary, .15 and .16; Unhappy, .15 and .10; Leading others into bad conduct, .14 and .10; Conduct prognosis bad, .14 and -.05; Disturbing influence in school, .13 and .16; Irresponsible, .13 and .17; Popular, .13 and .15; Attractive manner, .13 and .07; Lack of interest in school, .12 and .17; Gang, .11 (boys); Object of teasing, .11 and .14; Masturbation, .10 and .03; Grouped: lack of interest in school, .10 and .17; Leader, .09 and -.01; Over-interest in sex matters, .08 and .03; Temper display, .07 and .05; Listless, .07 and -.04; Oversuggestible, .07 and .14; Stuttering, .06 (boys); Bossy, .05 and .02; Exclusion from school, .05 and .12; Overinterest in opposite sex, .05 (girls); Inattentive in school, .04 and .03; Sex delinquency (coitus), .04 and -.15; Preference for younger children, .04 and -.08; Poor work in school, .04 and .04; Grouped: dull, slow, etc., .04 and .07; Enuresis, .03 and .11; Excuse-forming, .03 and .19; Underweight, .03 and .10; Hatred or jealousy of sibling, .02 and .06; Egocentric, .02 and .19; Follower, .01 and -.08; Repressed, .01 and .05; Speech defect, .00 and -.05; Slow, dull, -.00 and .09; Vocational guidance,

TABLE 50—Continued

-.00 and .10; Question of hypophrenia, -.02 and .06; Victim of sex abuse, -.03 (girls); Immoral home conditions, -.04 and .07; Feeble-minded sibling, -.05 and -.08; Absent-minded, -.06 and -.02; Retardation in school, -.12 and -.14

correlations in the .20's for boys: smoking, threatening violence, teasing other children, and complaining of bad treatment by other children. Seven notations among boys also showed moderate correlations in the .20's, with low coefficients below .20 for girls: truancy from home, fighting, stubbornness, rudeness, slovenliness, unpopularity, and vicious home conditions. A large list of eighteen miscellaneous notations among girls showed moderate correlations in the .20's, with corresponding low coefficients ranging from -.10 to .19 among boys: distractibility, inefficiency in work, play, etc., lack of initiative, laziness, loitering or wandering, nail-biting, destructiveness, quarrelsomeness, defiant attitude, truancy from school, selfishness, inferiority feelings, depressed mood or spells, daydreaming, seclusiveness, clean habits, former convulsions, and sex misbehavior denied entirely.

Four negative correlations of moderate size ranging from -.20 to -.27 were found with irregular sleep habits: among boys, bashfulness and lues and among girls sulkiness and brother in penal detention.

Among the six sex notations the only correlation of significant size with irregular sleep habits was for sex misbehavior denied entirely among girls,  $.28 \pm .06$ .

Among our seven physical or psychophysical notations there were the substantial correlations of  $.30 \pm .07$  and  $.44 \pm .09$  for boys and girls respectively with question or diagnosis of encephalitis. Among girls neurōlogical defect (unspecified) also showed a substantial correlation,  $.36 \pm .06$ . Lues among boys showed the moderate negative correlation of  $-.23 \pm .06$ .

Among home or familial notations there were two correlations of moderate size with irregular sleep habits, the positive correlation of  $.29 \pm .06$  among boys with vicious home conditions and the negative coefficient of  $-.23 \pm .07$  among girls with brother in penal detention.

## CHAPTER XXX

### EGOCENTRICITY AND SELFISHNESS

Staff notation of egocentric or self-centered attitude in our data was a formal notation made by the clinic's staff, usually by the psychiatrist, after examination of the patient, while selfishness was an informal descriptive term used by the "lay" informant. Egocentricity is an appraisal of a deep-lying personality trait, while selfishness is a mere description of overt behavior. Their intercorrelation among boys was only moderate,  $.21 \pm .04$ ; but among girls it was represented by one of the highest coefficients found for both of these notations,  $.45 \pm .05$ . The fact that among girls these "undesirable" traits showed moderate correlations in the .20's with intelligence quotient (IQ) is interesting, the corresponding boys' correlations being positive but low (Table 10, p. 130).

Staff notation of egocentric or self-centered attitude was noted among 287, or 13.6 per cent, of our 2,113 White boys and among 147, or 12.4 per cent, of our 1,181 White girls and was one of the most frequent of the formal staff notations employed in the clinic of the Illinois Institute for Juvenile Research during the years in which these children were examined. Its bi-serial correlations with the conduct-total were fairly high,  $.41 \pm .02$  for boys and  $.48 \pm .03$  for girls (Table 51). With the personality-total its correlation among girls was substantial,  $.30 \pm .03$ , but low among boys,  $.11 \pm .02$ . With the police-arrest criterion of juvenile delinquency its tetrachoric correlation among boys was only moderate,  $.20 \pm .03$ , and among girls negligible,  $.09 \pm .05$ .

Its highest correlations were found among girls. Boastful or "show-off" manner and excuse-forming attitude among girls yielded fairly high coefficients in the .40's with corresponding substantial coefficients among boys in the .30's. Selfishness, quarrelsomeness, and temper tantrums among girls also yielded large coefficients in the .40's, with moderate coefficients in the .20's among boys. Rudeness and bossy manner yielded substantial correlations in the .30's for both sexes, with a similar coefficient for

## Other Correlations (Positive to Negative)

Truancy from home, .19 and .13; Worry over specific fact, .19 and .18; Lack of interest in school, .18 and .06; Teasing other children, .18 (boys); Temper display, .18 and .07; Exclusion from school, .18 and .13; Loitering, .16 and -.02; Swearing (general), .16 (boys); Inferiority feelings, .16 and .18; Smoking, .15 (boys); Queer, .15 and .18; Complaining of bad treatment by other children, .15 (boys); Inattentive in school, .14 and .13; Nail-biting, .12 and .04; Mental conflict, .12 and .19; Refusal to attend school, .11 and .09; Unhappy, .11 and .17; Irresponsible, .10 and .15; Lues, .10 and .01; Masturbation, .09 and .14; Restless in sleep, .09 and .18; Inefficient in work, play, etc., .08 and .09; Sex delinquency (coitus), .08 and .07; Question of change of personality, .08 and .13; Preference for younger children, .08 and .15; Clean, .08 and .03; Grouped: depressed, etc., .08 and .19; Lazy, .06 and .05; "Nervous," .06 and .15; Crying spells, .05 and .19; Brother in penal detention, .05 and .08; Enuresis, .04 and .08; Listless, .04 and .05; Object of teasing, .04 and -.10; Former convulsions, .03 and .05; Victim of sex abuse, .03 (girls); Irregular sleep habits, .02 and .19; Seclusive, .02 and .09; Discard between parents, .00 and .01; Irregular attendance at school, -.00 and .01; Follower, -.01 and .06; Absent-minded, -.02 and .03; Bashful, -.02 and -.10; Repressed, -.02 and .13; Sex denied entirely, -.02 and .05; Neurological defect, -.03 and .16; Vocational guidance, -.05 and .02; Poor work in school, -.06 and .04; Stuttering, -.06 (boys); Popular, -.06 and .19; Grouped: dull, slow, -.06 and -.06; Lack of initiative, -.08 and .12; Slow, dull, -.09 and -.10; Attractive manner, -.09 and -.01; Immoral home conditions, -.09 and -.02; Apprehensive, -.10 and -.05; Feeble-minded sibling, -.10 and -.14; Headaches, -.11 and .07; Oversuggestible, -.14 and -.04; Underweight, -.14 and -.05

Omitted—Grouped: egocentric, etc.

threatening violence, which was computed for boys only. Contrari-ness showed correlations of  $.31 \pm .05$  for boys and  $.24 \pm .07$  for girls. Nine behavior difficulties among girls also yielded substantial correlations in the .30's, with moderate correlations in the .20's among boys: disobedience, defiant manner, incorrigibility, violence, sullenness, lying, fantastical lying, hatred or jealousy of sibling, and unpopularity. Three additional behavior problems among girls yielded substantial correlations in the .30's but low positive coefficients ranging from .14 to .17 among boys: stubbornness, staff notation of psychoneurotic trends (unspecified), and overinterest in sex matters.

Seven conduct notations showed moderate correlations in the .20's with egocentricity among both sexes: fighting, destructiveness, swearing or bad language (undifferentiated), disturbing influence in school, staying out late at night, leading others into bad conduct, and staff notation of unfavorable conduct prognosis and also with running with a gang which was calculated for boys only. Truancy from school and lack of interest or inattentiveness in school studies or employment (undifferentiated) also showed moderate correlations in the .20's among boys, but low correlations of .15 and .11 respectively among girls. A large group of seventeen miscellaneous notations among girls showed moderate coefficients in the .20's, the boys' coefficients being low or negligible: "leader", restlessness, irritable temperament, changeable moods or attitudes, emotional instability, distractibility, "spoiled child", stealing, bad companions, slovenliness, sulkiness, sensitiveness in general, sensitive over some specific fact, depressed mood or spells, daydreaming, finicky food habits, and question or diagnosis of encephalitis and also one calculated for girls only—overinterest in the opposite sex.

Four notations showed negative correlations of moderate size ranging from  $-.20$  to  $-.33$  with egocentricity, all among girls: question of hypophrenia, retardation in school, speech defect (other than stuttering), and vicious (not "immoral") home conditions, the boys' correlations being also negative but low, ranging from  $-.08$  to  $-.19$ .

Among the six sex notations, overinterest in sex matters among girls yielded the substantial correlation of  $.31 \pm .06$ , the boys' correlation being low, .14. Overinterest in the opposite

sex, which was calculated for girls only because of the paucity of boys' cases, showed a moderate correlation of  $.25 \pm .05$ . The correlations for sex delinquency (coitus), masturbation, sex misbehavior denied entirely, and (calculated for girls only) victim of sex abuse by older child or person showed low coefficients ranging from  $-.02$  to  $.14$ .

Among the seven physical or psychophysical notations there were two significant correlations of moderate size in the .20's, both among girls: the positive coefficient of  $.21 \pm .08$  with question or diagnosis of encephalitis, and the negative coefficient of  $-.26 \pm .06$  with speech defect (other than stuttering).

Among the four home or familial notations egocentricity showed only one correlation of significant size, the negative one of  $-.33 \pm .05$  with vicious home conditions among girls.

Selfishness was noted among 130 boys and 73 girls, the incidence for each sex being 6.2 per cent. Among girls its correlations with personality-total and conduct-total were meaningful,  $.44 \pm .03$  and  $.35 \pm .04$  respectively (Table 52). Among boys the corresponding coefficients were moderate,  $.25 \pm .03$  and  $.21 \pm .03$  respectively. With police arrest ("juvenile delinquency") the respective correlations for boys and girls were low,  $-.12 \pm .04$  and  $.15 \pm .06$ .

Its highest correlations were among girls: egocentricity,  $.45 \pm .05$ ; defiant attitude,  $.41 \pm .06$ ; fighting or quarrelsomeness (undifferentiated),  $.40 \pm .05$ ; and finicky food habits,  $.40 \pm .06$ . The corresponding correlations for boys were  $.21 \pm .04$ ,  $.21 \pm .05$ ,  $.22 \pm .04$ , and  $.13$ . Its correlation among boys with contrariness was  $.31 \pm .06$ , the girls' coefficient being negligible,  $-.01$ . Irritable temperament and boastful or "show-off" manner among girls yielded substantial correlations in the .30's, with corresponding moderate coefficients in the .20's among boys. Seven behavior problems among girls also yielded substantial correlations in the .30's but low coefficients below .20 among boys: quarrelsomeness, temper tantrums, stubbornness, changeable moods or attitudes, "spoiled child", irresponsibility, and psychoneurotic trends.

Selfishness among both sexes showed moderate correlations in the .20's with the five traits, bossy manner, temper display, disobedience, hatred or jealousy of sibling, and unpopularity.

## Other Correlations (Positive to Negative)

Sullen, .19 and .16; Smoking, .18 (boys); Sulky, .18 and -.02; Sensitive (general), .18 and .17; Distractible, .17 and .10; Nail-biting, .16 and .17; Truancy from home, .15 and .02; Mental conflict, .15 and .02; Grouped: depressed, etc., .15 and .17; Inefficient in work, play, etc., .14 and .19; "Nervous," .14 and .12; Worry over specific fact, .14 and .12; Lack of interest in school, .14 and .14; Disturbing influence in school, .13 and .15; Incurable, .13 and .18; Slowly, .13 and .06; Sex delinquency (coitus), .13 and -.13; Inferiority feelings, .13 and .17; Stealing, .12 and .11; Swearing (general), .12 (boys); Threatening violence, .12 (boys); Daydreaming, .12 and .09; Discord between parents, .12 and .11; Bashful, .11 and .11; Leader, .11 and .15; Attractive manner, .11 and .02; Masturbation, .09 and .18; Follower, .09 and .10; Lack of interest in school, .08 and .01; Refusal to attend school, .08 and .01; Absent-minded, .08 and .12; Queer, .08 and .19; Stuttering, .08 (boys); Clean, .08 and .12; Speech defect, .07 and .14; Truancy from school, .06 and .00; Victim of sex abuse, .06 (girls); Complaining of bad treatment by other children, .05 (boys); Poor work in school, .05 and -.02; Unhappy, .04 and -.15; Immoral home conditions, .04 and -.12; Grouped: dull, slow, etc., .04 and -.07; Overinterest in sex matters, .03 and .09; Headaches, .02 and .08; Lues, .02 and -.07; Overinterest in opposite sex, .02 (girls); Loitering, .01 and .01; Exclusion from school, .01 and .08; Listless, .00 and .11; Oversuggestible, -.00 and .12; Vicious home conditions, -.02 and -.17; Question of encephalitis, -.02 and .14; Object of teasing, -.02 and .06; Slow, -.02 and -.09; Bad companions, -.03 and .11; Underweight, -.04 and -.03; Vocational guidance, -.05 and .01; Former convulsions, -.05 and .04; Popular, -.05 and .07; Sex denied entirely, -.06 and .08; Enuresis, -.06 and .12; Staying out late at night, -.07 and .12; Apprehensive, -.09 and .09; Emotional instability, -.11 and .08; Retardation in school, -.13 and -.19; Brother in penal detention, -.13 and -.18

Teasing other children, which was calculated for boys only, showed a moderate correlation of  $.23 \pm .05$ . Seven behavior notations among boys showed moderate correlations in the .20's but low posi-

tive correlations below .20 among girls: rudeness, laziness, lack of initiative or ambition, restlessness, preference for younger children as playmates, seclusiveness, and staff notation of unfavorable conduct prognosis. Seventeen notations among girls showed moderate correlations in the .20's but low or negligible correlations below .20 among boys: violence, fighting, destructiveness, swearing or bad language (undifferentiated), leading others into bad conduct, excuse-forming attitude, lying, fantastical lying, restlessness in sleep, irregular sleep habits, inattentiveness in school, question of change of personality, sensitiveness or worrisomeness (undifferentiated), sensitiveness over some specific fact, depressed mood or spells, crying spells, and neurological defect (unspecified).

Among the six sex notations the only correlation of probable statistical significant size was with masturbation among girls, .18, all other coefficients being negligible and falling between -.13 and .13.

Neurological defect (unspecified) among girls showed the moderate correlation of .24 + .04, all our other correlations in the physical or psychophysical field being low or negligible.

Among the home or familial notations all correlations with selfishness were low or negligible.

When children noted as either "egocentric" by the clinic staff or "selfish" by the "lay" informant and also a handful of children manifesting a self-indulgent attitude<sup>1</sup> were grouped under one rubric, egocentricity or selfishness (undifferentiated), the resulting frequencies were 405 boys, or 19.2 per cent, and 211 girls, or 17.9 per cent. The correlation coefficients tended to resemble those of egocentricity (Table 51) more closely than those of selfishness (Table 52)—probably because the children noted as egocentric were more than twice as numerous in the composite group as those noted as selfish—but tended to be slightly larger than the corresponding correlations for either of the component notations. This fact indicates that the "broader grouping" in this instance tended to enhance the homogeneity of the dichotomies and was a justifiable procedure.<sup>2</sup>

Since the coefficients in Table 53 add little new information

## Other Correlations (Positive to Negative)

Truancy from school, .19 and .16; Worry over specific fact, .19 and .15; Exclusion from school, .18 and .09; Inferiority feelings, .18 and .11; Lack of interest in school, .18 and .12; Mental conflict, .16 and .08; Nail-biting, .16 and .10; Swearing (general), .16 (boys); Gang, .16 (boys); Lazy, .16 and .09; Complaining of bad treatment by other children, .14 (boys); Sex delinquency (coitus), .14 and .03; Loitering, .14 and .06; Grouped: depressed, etc., .14 and .18; Sulky, .13 and .19; Masturbation, .13 and .18; Unhappy, .13 and .10; Seclusive, .12 and .11; Refusal to attend school, .12 and .11; Emotional instability, .11 and .17; "Nervous," .07 and .14; Clean, .07 and .05; Irregular attendance at school, .06 and -.02; Discord between parents, .05 and .05; Follower, .04 and .09; Listless, .04 and .11; Former convulsions, .04 and -.02; Neurological defect, .03 and .14; Enuresis, .03 and .03; Absent-minded, .03 and .10; Object of teasing, .03 and -.10; Preference for younger children, .03 and .16; Victim of sex abuse, .03 (girls); Attractive manner, .02 and -.02; Brother in penal detention, .02 and .01; Bashful, .01 and -.03; Lack of initiative, .01 and -.07; Repressed, .01 and .05; Sex denied entirely, -.00 and .02; Poor work in school, -.01 and .02; Stuttering, -.02 (boys); Grouped: dull, slow, etc., -.02 and -.03; Question of encephalitis, -.03 and .18; Slow, dull, -.05 and -.06; Speech defect, -.05 and -.12; Vocational guidance, -.05 and .03; Immoral home conditions, -.06 and -.00; Popular, -.06 and .15; Lues, -.08 and -.06; Headaches, -.08 and .08; Underweight, -.10 and -.09; Apprehensive, -.10 and .01; Oversuggestible, -.10 and .08

Omitted—Selfish; Egocentric

beyond that afforded in Tables 51 and 52, a brief summary of the trends will be sufficient. Consistent correlations of fairly substantial size among both sexes and with both egocentricity and selfishness were found for boastful or "show-off" manner, bossy manner, defiant attitude, disobedience, hatred or jealousy for sibling, and unpopularity. Among boys contrariness and rudeness showed consistently substantial correlations, the girls' coefficients being variable or low. Among the girls, ten behavior difficulties showed consistent substantial correlations with both egocentricity and selfishness, the corresponding boys' coefficients being variable: quarrelsomeness, stubbornness, temper tantrums, excuse-forming attitude, lying, fantastical lying, "spoiled child," staff notation of psychoneurotic trends (unspecified), changeable moods or attitudes, and finicky food habits. Among the seventeen sex, physical, psychophysical, home, and familial notations considered in the present volume there were a few moderate correlations in the .20's with one of the two traits egocentricity and selfishness; but none of these seventeen notations showed significant correlations of .20 or more with both egocentricity and selfishness.

## CHAPTER XXXI

### EXCUSE-FORMING ATTITUDE

Excuse-forming attitude ("patient always blames others for his difficulties") was noted among 237, or 11.2 per cent, of our 2,113 White boys and among 99, or 8.4 per cent, of our 1,181 White girls. It showed large correlations of  $.44 \pm .02$  and  $.53 \pm .03$  with conduct-total for boys and girls respectively (Table 54). With police arrest among both sexes and personality-total among girls the coefficients were of moderate size, ranging from .22 to .27, while among boys the correlation with personality-total was low,  $.13 \pm .02$ .

Its highest correlations were among girls. Egocentricity and swearing or bad language (undifferentiated) among girls yielded large tetrachoric correlations in the .40's and substantial correlations in the .30's among boys. Fighting, quarrelsomeness, and disobedience or incorrigibility (undifferentiated) among girls also yielded large correlations in the .40's with corresponding moderate correlations in the .20's among boys.

Stealing and lying among both sexes yielded substantial correlations in the .30's. Threatening violence, which was calculated for boys only, also yielded a substantial correlation of  $.35 \pm .05$ . Five behavior problems among girls yielded substantial correlations in the .30's with corresponding moderate correlations in the .20's among boys: boastful or "show-off" manner, temper tantrums or display (undifferentiated), incorrigibility, disturbing influence in school, and truancy from home. Six additional behavior problems also showed substantial correlations in the .30's among girls but low positive coefficients below .20 among boys: temper tantrums, restlessness, inattentiveness in school, inefficiency in work, play, etc., rudeness, and sulkiness.

Seven personality and conduct problems showed moderate correlations in the .20's among both boys and girls: violence, staying out late at night, bad companions, slovenliness, changeable moods or attitudes, unpopularity, and overinterest in sex matters.

## Other Correlations (Positive to Negative)

Irresponsible, .17 and .18; Irritable, .17 and .10; Brother in penal detention, .16 and .05; Apprehensive, .15 and .04; Complaining of bad treatment by other children, .15 (boys); Mental conflict, .14 and -.05; Spoiled child, .14 and -.01; Refusal to attend school, .12 and .05; Gang, .12 (boys); Conduct prognosis bad, .11 and .05; Enuresis, .10 and .13; Lack of interest in school, .10 and .17; Masturbation, .10 and .11; Worry over specific fact, .10 and .04; Attractive manner, .10 and .05; Vicious home conditions, .10 and .01; Loitering, .09 and .13; Nail-biting, .09 and .04; Crying spells, .09 and .19; "Nervous," .09 and .05; Inferiority feelings, .09 and .17; Discord between parents, .09 and .10; Lazy, .08 and .14; Leader, .08 and .18; Object of teasing, .07 and .16; Restless in sleep, .07 and .16; Absent-minded, .06 and -.12; Former convulsions, .06 and -.08; Question of change of personality, .05 and .15; Poor work in school, .05 and .16; Depressed, .04 and .13; Victim of sex abuse, .04 (girls); Irregular sleep habits, .03 and .19; Clean, .03 and .06; Neurological defect, .03 and .15; Irregular attendance at school, .03 and .05; Speech defect, .03 and -.05; Immoral home conditions, .03 and -.06; Grouped: dull, slow, etc., .03 and .02; Finicky food habits, .12 and .14; Seclusive, .02 and .04; Sex denied entirely, .02 and .00; Slow, dull, .01 and .00; Psychoneurotic, .01 and .03; Popular, .00 and .14; Repressed, -.00 and .09; Listless, -.00 and -.03; Sensitive over specific fact, -.01 and -.14; Preference for younger children, -.01 and .02; Vocational guidance, -.01 and .04; Bashful, -.02 and -.07; Sex delinquency (coitus), -.04 and .09; Question of encephalitis, -.04 and .19; Lack of initiative, -.05 and -.01; Retardation in school, -.05 and -.10; Lues, -.05 and -.05; Underweight, -.06 and -.10; Stuttering, -.07 (boys); Headaches, -.08 and .07; Question of hypophrenia, -.11 and -.05

Smoking and teasing other children, which were calculated for boys only, and overinterest in the opposite sex, for which only the girls' correlations were computed, also showed moderate correlations in the .20's. Eight behavior traits among boys showed moderate correlations in the .20's but low positive correlations below .20 for girls: fantastical lying, oversuggestibility, "follower," sullenness, hatred or jealousy of sibling, truancy from school, leading others into bad conduct, and exclusion from school. Twelve behavior traits among girls showed moderate correlations in the .20's but low coefficients below .20 for boys: disobedience, stubbornness, contrariness, bossy manner, selfishness, temper display, emotional instability, distractibility, sensitiveness in general, unhappiness, daydreaming, and queer behavior.

Only one notation yielded a negative correlation of probable statistical significance, feeble-minded sibling among girls,  $-.20 \pm .06$ .

Among the six sex notations, moderate positive correlations in the .20's were found for overinterest in sex matters among both sexes and for overinterest in the opposite sex, which was calculated for girls only.

Among the seven physical or psychophysical notations and the four home or familial notations all obtained coefficients were low, falling between  $-.10$  and  $.19$ .

## CHAPTER XXXII

### STAFF NOTATION OF "UNFAVORABLE CONDUCT PROGNOSIS"

Staff notation of "unfavorable conduct prognosis" or similar notation by another clinic was a very important notation, since it embodies a formal composite staff prognosis of the child's future conduct after the clinical examination is completed. (It should be noted that no follow-up is involved in the present study to ascertain whether these prognoses were correct.) It was not frequently employed, appearing in only 78 cases, or 3.7 per cent, of our 2,113 White boys and in only 47 cases, or 4.0 per cent, of our 1,181 White girls. It was used to designate overt conduct difficulties rather than such "personality problems" as would not result in patent antisocial behavior. This notation was made typically among the older or adolescent children<sup>1</sup> and among children of lower intelligence (IQ).<sup>2</sup> Its correlations with IQ for boys and girls were -.18 and -.12 respectively (Table 10, p. 130).

With conduct-total its correlations for both boys and girls were large, the bi-serial correlations being  $.40 \pm .03$  and  $.46 \pm .04$  respectively (Table 55). With the police-arrest criterion of "juvenile delinquency" its tetrachoric correlation among girls,  $.47 \pm .06$ , was large, but among boys the corresponding coefficient was moderate,  $.29 \pm .05$ . With personality-total the correlations were quite moderate,  $.19 \pm .03$  and  $.22 \pm .05$ .

Among four behavior notations fairly large coefficients were found. The highest was for sex delinquency (coitus) among girls,  $.48 \pm .05$ , the boys' coefficient also being substantial,  $.32 \pm .08$ . Overinterest in the opposite sex among girls similarly yielded the large correlation of  $.43 \pm .05$ ; a corresponding coefficient for the boys was not computed because of the paucity of cases. Among boys the largest coefficients were  $.40$  for both emotional

<sup>1</sup>I, 207, Fig. 48.

## Other Correlations (Positive to Negative)

Swearing (general), .18 (boys); Irritable, .17 and -.04; Headaches, .17 and .11; Masturbation, .16 and .17; Neurological defect, .16 and .11; Grouped: temper, etc., .16 and .10; Rude, .14 and .13; Irregular sleep habits, .14 and -.05; Inferiority feelings, .14 and -.07; Complaining of bad treatment by other children, .14 (boys); Enuresis, .13 and .00; Sulky, .13 and .01; Temper display, .13 and -.05; Truancy from school, .13 and .12; Feeble-minded sibling, .13 and .15; "Nervous," .12 and -.01; Stubborn, .11 and .10; Truancy from home, .11 and .16; Excuse-forming, .11 and .03; Poor work in school, .11 and .01; Object of teasing, .10 and .08; Sensitive over specific fact, .10 and -.08; Absent-minded, .09 and .11; Apprehensive, .09 and -.02; Hatred or jealousy of sibling, .08 and -.05; Spoiled child, .07 and .12; Lues, .07 and .05; Speech defect, .07 and -.08; Nail-biting, .06 and .06; Queer, .06 and .09; Unhappy, .06 and -.02; Defiant, .05 and .16; Slovenly, .05 and .09; Bashful, .05 and -.07; Daydreaming, .05 and .11; Psychoneurotic, .05 and .18; Grouped: sensitive or worrisome, etc., .05 and -.07; Grouped: depressed, etc., .05 and .03; Retardation in school, .04 and .06; Brother in penal detention, .04 and .19; Underweight, .04 and -.15; Discord between parents, .04 and .05; Vicious home conditions, .03 and -.06; Leader, .02 and -.06; Depressed, .01 and .12; Preference for younger children, .01 and .14; Bossy, .00 and .02; Lack of interest in school, .00 and .16; Grouped: dull, slow, etc., -.00 and .16; Slow, dull, -.01 and .06; Seclusive, -.01 and .06; Grouped: lack of interest in school, etc., -.01 and .08; Lazy, -.02 and .01; Worry over specific fact, -.03 and -.00; Clean, -.03 and -.04; Attractive manner, -.04 and -.10; Irregular attendance at school, -.04 and -.03; Follower, -.05 and .05; Restless in sleep, -.06 and .11; Smoking, -.08 (boys); Vocational guidance, -.08 and -.17; Sensitive (general), -.10 and -.17; Immoral home conditions, -.11 and .01

instability and incorrigibility, the corresponding coefficients for girls being  $.32 \pm .08$  and  $.20 \pm .06$  respectively.

Exclusion from school among both sexes yielded substantial correlations in the .30's. Among boys violence and overinterest in sex matters likewise yielded substantial correlations in the .30's, with lesser corresponding correlations of  $.25 \pm .08$  and  $.15$  among girls. Among girls three conduct notations yielded substantial correlations in the .30's, with corresponding moderate coefficients in the .20's among boys: sullenness, fighting or quarrelsomeness (including violence, undifferentiated), and swearing or bad language (undifferentiated). Leading others into bad conduct and question or diagnosis of encephalitis also yielded substantial correlations in the .30's among girls but low positive correlations of  $.08$  and  $.13$  respectively among boys.

Six conduct and personality problems showed moderate correlations in the .20's for both sexes: stealing, staying out late at night, lying, egocentricity, restlessness, and oversuggestibility. Victim of sex attack or abuse by older child or person among girls showed the moderate correlation of  $.21 \pm .08$ , the corresponding coefficient for boys not being calculated because of paucity of boys' cases. Four similar moderate correlations in the .20's were found among boys for threatening violence, teasing other children, running with a gang, and stuttering, the coefficients for girls not being computed because of a paucity of girls' cases. Seven additional case-record notations among boys showed moderate correlations in the .20's but low correlations below  $.20$  among girls: bad companions, loitering or wandering, fighting, contrariness, selfishness, question of hypophrenia, and former convulsions. Sixteen notations among girls showed moderate correlations in the .20's but low correlations below  $.20$  among boys: disturbing influence in school, quarrelsomeness, temper tantrums, destructiveness, disobedience, fantastical lying, boastful or "show-off" manner, inefficiency in work, play, etc., irresponsibility, distractibility, listlessness, unpopularity, question of change of personality, changeable moods or attitudes, crying spells, and finicky food habits.

Four negative correlations of moderate size in the  $-.20$ 's were found among girls, the boys' coefficients being negligible: lack of initiative or ambition, inattentiveness in school, refusal

to attend school, and popularity. In three notations the tetrachoric  $r$ 's were not calculable because there were no instances in which both notations were made: sex misbehavior denied entirely among boys and mental conflict and repressed manner among girls. The corresponding coefficients for the other sex were low or negligible.

Among the six sex notations there were several coefficients of substantial or large size. Among girls we have noted that the highest correlation in Table 55 was with sex delinquency (coitus),  $.48 \pm .05$ , with the corresponding coefficient of  $.32 \pm .08$  among boys. For overinterest in the opposite sex, which was calculated for girls only, we noted the large correlation of  $.43 \pm .05$ . With overinterest in sex matters the boys' correlation of  $.33 \pm .07$  was substantial, the girls' coefficient being low,  $.15$ . With victim of sex abuse by older child or person, which was calculated for girls only, we noted the moderate correlation of  $.21 \pm .08$ .

Among the seven physical or psychophysical notations, question or diagnosis of encephalitis among girls yielded the substantial correlation of  $.35 \pm .10$ , the boys' coefficient being low,  $.13$ . For stuttering, which was calculated for boys only, there was an interesting correlation of moderate size,  $.28 \pm .07$ .

Among the four home or familial notations (discord between parents, brother in penal detention, and vicious and immoral home conditions) the correlations with staff notation of unfavorable conduct prognosis were all low, ranging from  $-.11$  to  $.19$ .

## CHAPTER XXXIII

### STEALING

Stealing was the most frequent of overt conduct difficulties noted among our cases, its incidence being 815, or 38.6 per cent, of our 2,113 White boys and 271, or 22.9 per cent, of our 1,181 White girls. Among boys its tetrachoric correlation with police arrest ("juvenile delinquency") was high,  $.63 \pm .02$ , its correlation among girls also being substantial,  $.37 \pm .04$  (Table 56). Among both sexes its bi-serial correlations of  $.55 \pm .01$  and  $.51 \pm .02$  with conduct-total were also high. With personality-total its correlations were low to moderate, the coefficients for girls and boys being  $.19 \pm .02$  and  $.29 \pm .03$  respectively. As an indicator of conduct deviation the importance of stealing is unquestioned, but its relation to personality problems appears to be relatively minor.

Lying among both sexes yielded very high tetrachoric correlations in the .60's. Among boys truancy from home and truancy from school also yielded very high correlations in the .60's, the corresponding coefficients for girls also being large or high,  $.54 \pm .03$  and  $.39 \pm .04$ .

Among boys, staying out late at night, associating with bad companions, and running with a gang yielded high correlations in the .50's. Among girls the coefficients for staying out late at night and bad companions were  $.39 \pm .04$  and  $.25 \pm .04$  respectively. For running with a gang the coefficients for girls were not calculated because of the paucity of cases. Defiant attitude among girls also yielded a high correlation of  $.51 \pm .04$ , the boys' coefficient being substantial,  $.32 \pm .03$ .

Incorrigibility and destructiveness among boys yielded large correlations in the .40's, with corresponding substantial coefficients in the .30's among girls. Smoking (calculated for boys only) yielded the large correlation of  $.43 \pm .03$ . Leading others into bad conduct among boys yielded the large coefficient of  $.46 \pm .03$  but among girls the low coefficient of .16. Among girls

Discord between parents, .18 and .12; Emotional instability, .18 and .09; Enuresis, .18 and .19; Victim of sex abuse, .18 (girls); Teasing other children, .17 (boys); Irregular sleep habits, .17 and .11; Complaining of bad treatment by other children, .17 (boys); Crying spells, .16 and .15; Restless, .15 and .19; Irregular attendance at school, .14 and -.04; Spoiled child, .13 and .05; Unhappy, .13 and .06; Changeable moods, .12 and .18; Hatred or jealousy of sibling, .12 and .10; Temper display, .12 and .13; Selfish, .12 and .11; Popular, .11 and -.01; Follower, .11 and -.03; Sex denied entirely, .10 and .10; Inferiority feelings, .10 and .07; Irritable, .10 and .01; Sulky, .10 and .14; Bashful, .09 and -.13; Repressed, .09 and .03; Preference for younger children, .08 and .18; Depressed, .07 and .18; Grouped: sensitive or worrisome, etc., .06 and .11; Clean, .06 and -.11; Absent-minded, .05 and .13; Grouped: depressed, etc., .02 and .12; Immoral home conditions, .02 and .11; Former convulsions, .02 and -.06; Object of teasing, .02 and .19; "Nervous," .02 and .07; Lazy, .01 and .11; Lues, .00 and -.02; Attractive manner, .00 and -.01; Listless, .00 and .08; Poor work in school, -.01 and -.05; Retardation in school, -.01 and -.04; Sensitive (general), -.02 and .06; Seclusive, -.02 and -.06; Slow, dull, -.02 and -.11; Apprehensive, -.02 and .13; Worry over specific fact, -.03 and .10; Headaches, -.03 and .10; Feeble-minded sibling, -.03 and -.10; Grouped: dull, slow, etc., -.03 and -.02; Neurological defect, -.04 and -.09; Finicky food habits, -.04 and .06; Question of hypophrenia, -.08 and -.08; Psychoneurotic, -.09 and .03; Speech defect, -.09 and -.05; Stuttering, -.10 (boys); Underweight, -.10 and -.02; Lack of initiative, -.12 and -.01

swearing or bad language (undifferentiated) and masturbation yielded large correlations in the .40's, with corresponding substantial correlations in the .30's for boys. Fighting among girls also yielded the large correlation of  $.40 \pm .03$ , the boys' coefficient being of moderate size,  $.28 \pm .03$ .

Three conduct difficulties yielded substantial correlations in the .30's for both sexes: loitering or wandering, excuse-forming attitude, and fantastical lying. Overinterest in the opposite sex among girls similarly yielded the substantial correlation of  $.31 \pm .04$ , the boys' coefficient not being computed because of a paucity of cases. Boastful or "show-off" manner and oversuggestibility among boys yielded substantial correlations in the .30's, the girls' correlations being somewhat lower,  $.24 \pm .05$  and  $.13$  respectively. Four additional notations among girls also yielded substantial correlations in the .30's, with moderate coefficients in the .20's among boys: violence, sullenness, slovenliness, and exclusion from school. Three personality problems among girls yielded similarly substantial correlations in the .30's but low positive correlations below .20 among boys: restlessness in sleep, queer behavior, and unpopularity.

Five notations showed moderate correlations in the .20's with stealing among both sexes: disobedience, disturbing influence in school, rudeness, irresponsibility, and staff notation of unfavorable conduct prognosis. Among boys threatening violence also showed a moderate correlation of  $.24 \pm .04$ , the girls' coefficient not being computed because of the fewness of cases. Three notations among boys similarly showed moderate correlations in the .20's, with low positive coefficients below .20 among girls: temper tantrums or display (undifferentiated), refusal to attend school, and brother in penal detention. Among girls there was a large list of twenty miscellaneous case notations showing moderate correlations in the .20's but low positive correlations below .20 among boys: contrariness, stubbornness, egocentricity, quarrelsomeness, bossy manner, temper tantrums, "nervousness" or restlessness (including irritable temperament and changeable moods or attitudes, undifferentiated), nail-biting, distractibility, day-dreaming, sensitiveness over some specific fact, question of change of personality, inattentiveness in school, lack of interest in school, inefficiency in work, play, etc., sex delinquency (coitus),

overinterest in sex matters, "leader," question or diagnosis of encephalitis, and vicious home conditions. (The coefficient of  $.20 \pm .10$  among girls for mental conflict is of doubtful reliability because of its large probable error.)

The only significant negative correlations were found with the notation "request for vocational guidance,"  $-.22 \pm .02$  and  $-.31 \pm .04$  among boys and girls respectively.

Among the six sex notations several positive correlations of moderate and substantial size with stealing were found. Masturbation showed the considerable coefficients of  $.32 \pm .02$  and  $.44 \pm .04$  for boys and girls respectively. Among girls there were moderate correlations in the .20's for sex delinquency (coitus) and overinterest in sex matters. The substantial correlation of  $.31 \pm .04$  with overinterest in the opposite sex was found among girls, the boys' correlation not being computed because of paucity of cases.

Among the seven physical or psychophysical notations the only statistically significant correlation was  $.26 \pm .06$  with question or diagnosis of encephalitis among girls. The correlations of  $.18$  and  $.19$  with enuresis may also be considered as suggestive.

Among the four home or familial notations there were two correlations of moderate size with stealing: among boys for brother in penal detention,  $.28 \pm .03$ , and among girls for vicious home conditions,  $.24 \pm .05$ .

## CHAPTER XXXIV

### TRUANCY FROM HOME AND STAYING OUT LATE AT NIGHT

The fact that truancy from home and staying out late at night are very similar notations is shown by the fact of their high intercorrelation, the tetrachoric coefficients being  $.62 \pm .02$  and  $.53 \pm .04$  for boys and girls respectively (Table 57), and by the general similarity of their "outside correlations" with numerous other notations. From the standpoint both of juvenile delinquency and of undesirable conduct manifestation they are of grave importance, the bi-serial and tetrachoric  $r$ 's ranging from  $.42$  to  $.68$ . With personality deviations as measured by personality-total their importance is relatively minor, the bi-serial coefficients ranging from  $.16$  to  $.24$ .

Truancy from home was noted among 503 cases, or 23.8 per cent, of our 2,113 White boys and among 189, or 16.0 per cent, of our 1,181 White girls. It was one of the most frequently occurring conduct problems in our data.

Its highest correlations among both sexes were with stealing and staying out late at night, the boys' correlations being  $.64 \pm .02$  and  $.62 \pm .02$  respectively and the girls' correlations being  $.54 \pm .03$  and  $.53 \pm .04$  respectively. Truancy from school among boys also yielded the very high correlation of  $.61 \pm .02$ , the girls' coefficient also being large,  $.48 \pm .04$ . Loitering or wandering among boys yielded the high correlation of  $.53 \pm .03$ , with a moderate correlation of  $.25 \pm .06$  among girls. Lying and incorrigibility among both sexes yielded fairly high correlations in the .40's. Smoking yielded a large correlation of  $.42 \pm .03$  among boys, the coefficients for the girls not being computed because of fewness of cases. Bad companions among boys yielded a similarly large correlation of  $.47 \pm .02$ , the girls' coefficient being moderate,  $.21 \pm .05$ . Fantastical lying yielded very substantial correlations of  $.38 \pm .04$  and  $.40 \pm .05$  for boys and girls

## Other Correlations (Positive to Negative)

Oversuggestible, .19 and .17; Egocentric, .19 and .13; Irregular attendance at school, .18 and -.13; Temper tantrums, .17 and .16; Grouped: temper, etc., .17 and .11; Queer, .16 and .19; Lack of interest in school, .15 and .11; Selfish, .15 and .02; Sulky, .15 and .14; Threatening violence, .15 (boys); Grouped: lack of interest in school, .15 and .11; Nail-biting, .14 and .16; Mental conflict, .14 and -.05; Discord between parents, .14 and .10; Enuresis, .13 and -.00; Unpopular, .13 and .16; Feeble-minded sibling, .13 and -.12; Teasing other children, .12 (boys); Quarrelsome, .12 and .08; Hatred or jealousy of sibling, .12 and .09; Leader, .12 and -.07; Conduct prognosis bad, .11 and .16; Former convulsions, .11 and -.07; Bossy, .10 and .05; Inattentive in school, .10 and .07; Irritable, .10 and -.11; Inefficient in work, play, etc., .09 and .13; Emotional instability, .09 and .18; Popular, .09 and .03; Restless in sleep, .08 and .16; Lazy, .08 and -.05; Seclusive, .08 and .01; Crying spells, .08 and .03; Grouped: "nervous," etc., .08 and .11; Spoiled child, .07 and .07; Headaches, .07 and .11; Grouped: depressed, etc., .06 and .10; Absent-minded, .04 and .06; Daydreaming, .04 and .15; Overinterest in sex matters, .04 and .10; Sensitive over specific fact, .04 and .05; Finicky food habits, .03 and .02; Changeable moods, .03 and .17; Inferiority feelings, .03 and .02; Attractive manner, .01 and -.08; Repressed, .01 and -.01; Preference for younger children, .00 and -.01; Poor work in school, -.00 and -.09; Follower, -.01 and -.01; "Nervous," -.02 and .12; Clean, -.02 and -.16; Underweight, -.02 and -.06; Object of teasing, -.03 and .15; Question of hypophrenia, -.03 and -.05; Retardation in school, -.03 and -.05; Grouped: sensitive or worrisome, etc., -.04 and -.02; Apprehensive, -.05 and .14; Listless, -.05 and -.10; Neurological defect, -.05 and .01; Lues, -.05 and .16; Lack of initiative, -.06 and -.03; Speech defect, -.06 and -.14; Immoral home conditions, -.07 and .11; Psychoneurotic, -.08 and .05; Grouped: dull, slow, etc., -.08 and -.05; Slow, dull, -.09 and -.04; Stuttering, -.09 (boys); Worry over specific fact, -.10 and -.02; Depressed, -.11 and .07; Bashful, -.13 and -.19

respectively. Sex delinquency (coitus) among girls likewise yielded the important correlation of  $.48 \pm .04$  with truancy from home, but among boys this relationship was low, .16.

Running with a gang, which was computed for boys only, and overinterest in the opposite sex, which was computed for girls only, yielded substantial correlations in the .30's. Leading others into bad conduct and disobedience among boys similarly yielded substantial correlations in the .30's, with only moderate correlations of  $.21 \pm .06$  and  $.19$  respectively among girls. Destructiveness showed an interesting divergence in its correlations, the boys' correlation being  $.31 \pm .03$ , while the corresponding girls' coefficient was negative,  $-.16$ . Four conduct problems among girls yielded substantial correlations in the .30's, with moderate coefficients in the .20's among boys: refusal to attend school, excuse-forming attitude, fighting, and swearing or bad language (undifferentiated).

Five notations showed moderate correlations in the .20's for both sexes: defiant attitude, violence, rudeness, slovenliness, and exclusion from school. Complaining of bad treatment by other children, which was calculated for boys only, and victim of sex abuse by older child or person, which was calculated for girls only, showed moderate correlations in the .20's. Eight notations among boys showed moderate correlations in the .20's but low positive correlations below .20 among girls: irregular sleep habits, contrariness, sullenness, irresponsibility, disturbing influence in school, egocentricity or selfishness (undifferentiated), unhappiness, and brother in penal detention. Seven miscellaneous notations among girls showed moderate correlations in the .20's but low positive correlations below .20 among boys: stubbornness, temper display, boastful or "show-off" manner, distractibility, restlessness, question or diagnosis of encephalitis, and vicious home conditions.

With truancy from home there were three negative correlations of moderate size in the  $-.20$ 's, all among girls: sensitivity in general, sex misbehavior denied entirely, and "request for vocational guidance."

Among the six sex notations there were several correlations of significant size, all among girls, the corresponding boys' coefficients ranging from  $.04$  to  $.19$ : for sex delinquency (coitus) the large correlation of  $.48 \pm .04$ , for masturbation the substantial correlation of  $.35 \pm .04$ , for overinterest in the opposite sex and victim of sex abuse by older child or person the very substantial

coefficients of  $.33 \pm .04$  and  $.28 \pm .05$  respectively, the corresponding coefficients for boys being omitted because of paucity of cases, and for sex misbehavior denied entirely the negative coefficient of  $-.24 \pm .06$ .

The correlations for the seven physical or psychophysical notations were all low or negligible, except for question or diagnosis of encephalitis among girls, which showed a moderate correlation of  $.24 \pm .07$ .

Among the four home or familial notations there were two coefficients of moderate size, brother in penal detention among boys,  $.23 \pm .04$ , and vicious home conditions among girls,  $.21 \pm .06$ .

Staying out late at night was noted among 319, or 15.1 per cent, of our boys and among 140, or 11.9 per cent, of our girls.

Its highest correlation was with truancy from home among boys,  $.62 \pm .02$ , with a similarly high correlation among girls,  $.53 \pm .04$  (Table 58). Truancy from school also showed high coefficients in the .50's for both sexes. Overinterest in the opposite sex, which was computed for girls only, likewise yielded the high correlation of  $.50 \pm .04$ . Bad companions among girls yielded the high correlation of  $.59 \pm .04$ , with a corresponding large coefficient of  $.44 \pm .03$  among boys. Stealing among boys yielded the high correlation of  $.50 \pm .02$ , with a corresponding substantial coefficient of  $.39 \pm .04$  among girls.

Incorrigibility and loitering or wandering among both sexes yielded large correlations ranging from .46 to .49. Swearing or bad language (undifferentiated) yielded substantial or large correlations of  $.31 \pm .03$  and  $.48 \pm .05$  for boys and girls respectively. Among girls sex delinquency (coitus) and vicious home conditions likewise yielded high correlations in the .40's but low coefficients of .10 and .14 respectively among boys.

Substantial correlations in the .30's among both sexes were found for disobedience, leading others into bad conduct, and lying and also for two conduct difficulties which were computed only for boys, running with a gang and smoking. Irresponsibility among boys yielded the substantial correlation of  $.33 \pm .04$  but a low correlation of .13 among girls. Defiant attitude yielded the moderate or substantial correlations of  $.27 \pm .04$  and  $.35 \pm .05$  among boys and girls respectively. Among girls three behavior

## Other Correlations (Positive to Negative)

Inefficient in work, play, etc., .19 and .08; Complaining of bad treatment by other children, .18 (boys); Disturbing influence in school, .17 and .06; Popular, .17 and .04; Exclusion from school, .16 and .08; Sullen, .15 and .13; Sex denied entirely, .15 and .02; Teasing other children, .14 (boys); Sulky, .14 and .03; Masturbation, .14 and .11; Contrary, .13 and .11; Queer, .13 and .19; Restless, .13 and .15; Sensitive over specific fact, .13 and .03; Discord between parents, .13 and .16; Inattentive in school, .12 and .18; Daydreaming, .12 and .18; Brother in penal detention, .12 and -.05; Quarrelsomeness, .11 and .15; Hatred or jealousy of sibling, .11 and .08; Spoiled child, .11 and .19; Victim of sex abuse, .11 (girls); Overinterest in sex matters, .08 and .01; Apprehensive, .08 and .17; Crying spells, .08 and .11; Bossy, .07 and .11; Finicky food habits, .07 and .13; Enuresis, .07 and .15; Object of teasing, .07 and .14; Irregular attendance at school, .07 and .05; Nail-biting, .06 and .07; Absent-minded, .06 and -.18; Psychoneurotic, .06 and -.03; Inferiority feelings, .06 and .12; Grouped: depressed, etc., .06 and .13; Grouped: "nervous," etc., .05 and .05; Lack of initiative, .04 and -.06; Former convulsions, .04 and .01; Speech defect, .04 and -.17; Immoral home conditions, .04 and .14; Lazy, .02 and .05; Seclusive, .02 and -.03; Attractive manner, .02 and .02; Mental conflict, .01 and .13; Retardation in school, .01 and -.09; Stuttering, .01 (boys); Follower, .01 and .01; Grouped: sensitive or worrisome, etc., .01 and .01; Irritable, .00 and .11; Underweight, .00 and .02; Clean, -.01 and -.07; Question of hypophrenia, -.01 and -.04; Distractible, -.01 and .12; Changeable moods, -.01 and .17; Restless in sleep, -.02 and .18; Listless, -.02 and -.09; Preference for younger children, -.03 and -.04; "Nervous," -.03 and .06; Slow, dull, -.04 and -.13; Grouped: dull, slow, etc., -.04 and -.12; Headaches, -.05 and -.05; Feeble-minded sibling, -.06 and -.11; Selfish, -.07 and .12; Repressed, -.08 and -.19; Lues, -.08 and .09; Neurological defect, -.09 and .09; Bashful, -.10 and -.13; Depressed, -.11 and .09; Sensitive (general), -.15 and -.05; Worry over specific fact, -.16 and .02

problems similarly yielded substantial correlations in the .30's but low coefficients below .20 among boys: violence, question of change of personality, and poor work in school.

Ten behavior problems showed moderate correlations in the .20's with staying out late at night among both sexes: irregular

sleep habits, refusal to attend school, oversuggestibility, excuse-forming attitude, fantastical lying, egocentricity, rudeness, destructiveness, unpopularity, and staff notation of unfavorable conduct prognosis. Threatening violence (calculated only for boys) also showed the moderate correlation of  $.25 \pm .05$ . Six behavior traits among boys showed moderate correlations in the .20's but low coefficients below .20 among girls: fighting, boastful or "show-off" manner, unhappiness, emotional instability, slovenliness, and "leader." Among girls five notations showed moderate correlations in the .20's, the coefficients for boys being below .20: lack of interest in school, stubbornness, temper tantrums, temper display, and question or diagnosis of encephalitis.

The notation "request for vocational guidance" showed the moderate negative correlation of  $-.23 \pm .04$  among girls with staying out late at night.

Among the six sex notations two very significant correlations, both among girls, were with sex delinquency (coitus),  $.44 \pm .04$ , and overinterest in the opposite sex,  $.50 \pm .04$  (calculated for girls only). The remaining coefficients in this field were positive but low, ranging from .02 to .15.

Among the seven physical or psychophysical notations, the only statistically significant coefficient was the moderate one of  $.21 \pm .08$  with question or diagnosis of encephalitis among girls.

Among the four home or familial notations the only significant correlation with staying out late at night was the very substantial one of  $.41 \pm .06$  with vicious home conditions among girls.

(Since the correlations discussed in this chapter tended to be similar to those for truancy from school and refusal to attend school, a further summary will be found at the end of the next chapter.)

## CHAPTER XXXV

### TRUANCY FROM SCHOOL AND REFUSAL TO ATTEND SCHOOL

Truancy from school was so highly intercorrelated with truancy from home and staying out late at night (the tetrachoric  $r$ 's ranging from .48 to .61) and other "outside correlations" with other notations were so similar that all three conduct problems must be considered to be closely interrelated (Table 59). It was a grave indicator of conduct disorder, its correlations with conduct-total and police arrest ranging from .42 to .57, but of minor importance as to personality deviation. It was one of the most frequent of the conduct problems among our clinic cases, occurring among 675 (or 31.9 per cent) of our 2,113 White boys and among 143 (or 12.1 per cent) of our 1,181 White girls.

The highest correlations for truancy from school were among boys, the tetrachoric  $r$ 's with stealing and truancy from home being  $.62 \pm .02$  and  $.61 \pm .02$  respectively. Among girls the corresponding coefficients of  $.39 \pm .04$  and  $.48 \pm .04$  were also very substantial. For girls the highest correlations were with staying out late at night ( $.54 \pm .04$ ) and refusal to attend school ( $.54 \pm .06$ ), the corresponding coefficients of  $.50 \pm .02$  and  $.44 \pm .03$  for boys also being large or high.

Bad companions and lying yielded large correlations in the .40's among both sexes. Running with a gang and smoking, which were computed only for boys, and overinterest in the opposite sex, which was computed only for girls, also yielded large correlations in the .40's. Two additional conduct problems yielded correlations almost as large: loitering or wandering, with its coefficients of  $.49 \pm .03$  and  $.39 \pm .06$  for boys and girls respectively, and incorrigibility, with corresponding correlations of  $.37 \pm .02$  and  $.42 \pm .04$ .

Four conduct traits among boys yielded substantial correlations in the .30's, the girls' coefficients being of moderate size in the .20's: irregular attendance at school, leading others

## Other Correlations (Positive to Negative)

Contrary, .19 and -.01; Complaining of bad treatment by other children, .19 (boys); Grouped: fighting, etc., .19 and .18; Grouped: egocentric, etc., .19 and .16; Inattentive in school, .18 and .16; Nail-biting, .17 and .17; Threatening violence, .17 (boys); Hatred or jealousy of sibling, .17 and .04; Enuresis, .15 and .12; Irresponsible, .14 and .04; Leader, .14 and .14; Discord between parents, .13 and .10; Conduct prognosis bad, .13 and .12; Masturbation, .13 and .19; Inefficient in work, play, etc., .12 and .02; Sulky, .12 and .15; Unpopular, .12 and .17; Grouped: temper, etc., .11 and .15; Temper display, .11 and .09; Stubborn, .11 and .18; Victim of sex abuse, .11 (girls); Crying spells, .10 and .07; Retardation in school, .10 and -.03; Follower, .10 and -.01; Grouped: "nervous," etc., .09 and .10; Former convulsions, .09 and -.06; Spoiled child, .09 and .16; Lazy, .09 and .06; Bossy, .06 and .14; Selfish, .06 and .00; Restless, .06 and .17; Absent-minded, .06 and .03; Irritable, .06 and .08; Question of encephalitis, .06 and .09; Headaches, .05 and .05; Popular, .05 and -.12; Poor work in school, .05 and .06; Unhappy, .05 and .08; Emotional instability, .05 and .13; Apprehensive, .05 and .19; Quarrelsome, .04 and .01; Lues, .03 and .10; Clean, .03 and -.16; Mental conflict, .03 and .12; Object of teasing, .03 and .17; Queer, .02 and .13; Seclusive, .02 and .05; Attractive manner, .02 and .12; Sensitive over specific fact, .01 and .16; "Nervous," .01 and .04; Slow, dull, .01 and -.13; Overinterest in sex matters, .01 and .19; Teasing other children, .01 (boys); Finicky food habits, .00 and .11; Repressed, .00 and .09; Grouped: dull, slow, etc., .00 and -.09; Restless in sleep, -.00 and .10; Preference for younger children, -.01 and .11; Grouped: depressed, etc., -.01 and .03; Lack of initiative, -.02 and -.11; Speech defect, -.02 and -.05; Underweight, -.02 and -.00; Inferiority feelings, -.02 and .06; Changeable moods, -.02 and -.01; Distractable, -.03 and .07; Question of hypophrenia, -.03 and -.06; Feeble-minded sibling, -.06 and .01; Depressed, -.08 and .02; Sensitive (general), -.08 and .05; Stuttering, -.10 (boys); Listless, -.10 and -.09; Psychoneurotic, -.11 and -.03; Neurological defect, -.13 and -.04; Bashful, -.14 and -.04

into bad conduct, disobedience, and fighting. Brother in penal detention among boys yielded likewise a substantial correlation of  $.32 \pm .03$ , the girls' coefficient being comparatively low, .18. Among girls defiant attitude, swearing or bad language (undifferentiated), and fantastical lying yielded substantial correlations

in the .30's with moderate coefficients in the .20's among boys. Among girls sex delinquency (coitus), disturbing influence in school, and vicious home conditions also yielded substantial correlations in the .30's but low positive coefficients below .20 for boys.

Seven notations showed moderate correlations in the .20's with truancy from school among both sexes: exclusion from school, lack of interest in school, sullenness, rudeness, boastful or "show-off" manner, slovenliness, and destructiveness. Four notations among boys showed moderate correlations in the .20's but low coefficients below .20 among girls: egocentricity, excuse-forming attitude, oversuggestibility, and sex misbehavior denied entirely. Eight miscellaneous notations among girls similarly showed moderate correlations in the .20's but low coefficients below .20 among boys: violence, temper tantrums, question of change of personality, daydreaming, sensitiveness or worrisomeness (undifferentiated), worry over some specific fact, irregular sleep habits, and immoral home conditions.

The only negative correlation of moderate size was for "request for vocational guidance" among girls,  $-.25 \pm .05$ .

Among the six sex notations substantial correlations with truancy from school were found among girls for sex delinquency (coitus),  $.36 \pm .04$ , and for overinterest in the opposite sex,  $.42 \pm .04$ . Among boys sex misbehavior denied entirely showed the moderate correlation of  $.21 \pm .04$ . All other correlations in this field were positive but low, ranging from .01 to .19.

All correlations in the physical or psychophysical field were low or negligible, ranging from  $-.13$  to  $.15$ .

Among the four home or familial notations, truancy from school yielded substantial correlations in the .30's for brother in penal detention among boys and vicious home conditions among girls and a moderate coefficient of  $.20 \pm .06$  for immoral home conditions among girls. All other correlations in this field were positive and low, ranging from .05 to .18.

Refusal or marked unwillingness to attend school was fairly highly correlated with truancy from school, the tetrachoric  $r$ 's for boys and girls being  $.44 \pm .03$  and  $.54 \pm .06$  respectively (Table 60). It was noted among 145 boys, or 6.9 per cent, and among 46

Disturbing influence in school, .19 and .08; Temper tantrums, .19 and .17; Complaining of bad treatment by other children, .17 (boys); Grouped: fighting, etc., .19 and .06; Irresponsible, .18 and -.01; Destructive, .17 and .13; Disobedient, .17 and .12; Sulky, .17 and .10; Emotional instability, .17 and .04; Temper display, .16 and .05; Apprehensive, .16 and .19; Daydreaming, .16 and .12; Popular, .16 and .18; Brother in penal detention, .16 and .16; Rude, .15 and .13; Threatening violence, .15 (boys); Oversuggestible, .15 and -.07; Grouped: temper, etc., .15 and .08; Bad companions, .14 and .14; Overinterest in sex matters, .14 and .14; Hatred or jealousy of sibling, .14 and .14; Depressed, .14 and -.13; Listless, .14 and -.06; Psychoneurotic, .14 and .04; Irritable, .14 and .09; Seclusive, .14 and .18; Unpopular, .14 and -.00; Poor work in school, .14 and .16; Inefficient in work, play, etc., .13 and -.03; Crying spells, .13 and .00; Follower, .13 and .00; Lying, .12 and .16; Teasing other children, .12 (boys); Absent-minded, .12 and .16; Excuse-forming, .12 and .05; Grouped: egocentric, etc., .12 and .11; Changeable moods, .11 and -.03; Egocentric, .11 and .09; Object of teasing, .11 and -.01; Worry over specific fact, .10 and .03; Repressed, .10 and -.08; Question of encephalitis, .10 and .19; Discord between parents, .10 and .06; Grouped: "nervous," etc., .10 and -.03; Slovenly, .09 and -.07; Restless, .09 and .02; Sensitive (general), .09 and .13; Leader, .09 and .15; Headaches, .09 and .14; Boastful, "show-off," .08 and .00; Inattentive in school, .08 and -.08; Selfish, .08 and .01; Former convulsions, .08 and .01; Fantastical lying, .07 and .14; Distractible, .07 and .08; Mental conflict, .07 and .13; Masturbation, .06 and .02; Sensitive over specific fact, .06 and .19; Sex denied entirely, .06 and .19; Lazy, .05 and .04; Nail-biting, .05 and -.06; Lack of initiative, .05 and -.18; "Nervous," etc., .05 and -.10; Grouped: dull, slow, etc., .05 and -.12; Sex delinquency (coitus), .05 and -.01; Grouped: sensitive or worrisome, etc., .04 and .15; Restless in sleep, .03 and .09; Lues, .03 and .10; Immoral home conditions, .03 and .00; Inferiority feelings, .02 and .18; Stuttering, .02 (boys); Attractive manner, .02 and -.11; Neurological defect, .02 and -.18; Quarrelsomeness, .02 and .03; Slow, dull, .01 and -.07; Bashful, .00 and .00; Question of hypophrenia, -.00 and -.07; Preference for younger children, -.01 and .07; Victim of sex abuse, -.02 (girls); Vicious home conditions, -.02 and -.06; Retardation in school, -.03 and -.09; Speech defect, -.04 and -.10; Bossy, -.06 and -.09; Enuresis, -.07 and .12; Underweight, -.08 and .11

girls, or 3.9 per cent. In contrast with truancy from home or from school, its importance as an indicator either of conduct disorder or of overt juvenile delinquency was only moderate, the correlations ranging from .07 to .30. As a correlate of personality deviation its importance was very minor, the bi-serial  $r$ 's for boys and girls being only  $.17 \pm .03$  and  $.08 \pm .04$ .

Its highest correlations were with truancy from school, with coefficients of  $.44 \pm .03$  and  $.54 \pm .06$  for boys and girls respectively. Irregular attendance at school yielded substantial correlations in the .30's for both sexes. Loitering or wandering yielded the substantial correlation of  $.36 \pm .05$  among boys but a low coefficient of .13 among girls. Truancy from home among girls

yielded the substantial correlation of  $.31 \pm .06$ , the corresponding coefficient among boys being practically as large,  $.28 \pm .04$ . Three behavior problems among girls—lack of interest in school, defiant attitude, and finicky food habits—similarly yielded substantial correlations in the .30's but low coefficients below .20 for boys.

Among both sexes refusal to attend school showed moderate correlations in the .20's with four behavior difficulties: staying out late at night, incorrigibility, irregular sleep habits, and question of change of personality. Three conduct problems, for which only the boys' correlations were computed because of the paucity of girls' cases: running with a gang, swearing in general, and smoking, and one computed only for girls, overinterest in the opposite sex, also showed moderate correlations in the .20's. Eight notations among boys showed moderate correlations in the .20's but low positive coefficients below .20 among girls: exclusion from school, stealing, fighting, stubbornness, contrariness, violence, leading others into bad conduct, and queer behavior. Five notations among girls similarly showed moderate correlations in the .20's but low positive coefficients below .20 among boys: sullenness, swearing or bad language (undifferentiated), "spoiled child," clean habits, and "request for vocational guidance."

Negative correlations of moderate size in the -.20's were found among boys for feeble-minded sibling and among girls for unhappiness and staff notation of unfavorable conduct prognosis.

Among the six sex notations in our data the only coefficient with a claim to statistical significance was for overinterest in the opposite sex (calculated for girls only),  $.21 \pm .07$ .

Among the seven physical or psychophysical notations and among the four home or familial notations all twenty-two correlations with refusal to attend school were low or negligible, ranging from  $-.18$  to  $.19$ .

Since the four conduct traits discussed in chapters xxxiv and xxxv—truancy from home, staying out late at night, truancy from school, and refusal to attend school—appear to form a fairly closely interrelated group, we may summarize certain trends among the correlations. The following six behavior traits showed, in the main, substantial to high correlations with all four notations,

ranging from the .20's to the .60's, among both sexes: stealing, loitering or wandering, incorrigibility, and swearing or bad language (undifferentiated) and also running with a gang and smoking, for which only the boys' correlations were computed. The four conduct problems, leading others into bad conduct, fighting, violence, and defiant attitude, tended to yield moderate to substantial correlations in the .20's and .30's for all four notations among both sexes and among boys also sullenness and irregular sleep habits.

With the three notations, truancy from home and from school, and staying out late at night, two conduct problems, associating with bad companions and lying, tended to yield substantial to large correlations, ranging from the .20's to the .50's. Disobedience, fantastical lying, and excuse-forming attitude similarly tended to yield moderate to substantial correlations in the .20's and .30's with these three notations. Among girls, sex delinquency (coitus) and overinterest in the opposite sex (computed only for girls) yielded substantial to large correlations ranging from .33 to .50 with all three notations. With these three notations vicious home conditions among girls yielded moderate to substantial correlations ranging from .21 to .41. Vicious home conditions among boys and immoral home conditions among both sexes tended to show low or negligible correlations ranging from -.07 to .20.

## CHAPTER XXXVI

### DISOBEDIENCE; INCORRIGIBILITY; DEFIANCE; STUBBORNNESS; AND CONTRARINESS

That the five conduct problems discussed in this chapter—disobedience, incorrigibility, defiant attitude, stubbornness, and contrariness—are closely interrelated is indicated by the fact of their generally large intercorrelation and also by the fact of the similarity of their "outside correlations" with other traits. The first three of these traits—disobedience, incorrigibility, and defiant attitude—are especially closely intercorrelated, the tetrachoric  $r$ 's ranging from .41 to .52. Stubbornness and contrariness are less closely intercorrelated with the other three traits, their coefficients ranging from .16 to .44. In view of their frequency of occurrence and their relatively high importance as indicators of behavior deviation, it seemed advisable to consider each of the five notations separately as well as under one rubric, disobedience or incorrigibility (undifferentiated).

All five notations were notably important as indicators of conduct difficulties, their bi-serial  $r$ 's with conduct-total ranging from .25 to .68. As indicators of overt juvenile delinquency or of undesirable personality traits their importance is not so great, their correlations with police arrest and personality-total ranging from .08 to .53.

Disobedience was noted among 459 of our 2,113 White boys (21.7 per cent) and among 207 of our 1,181 White girls (17.5 per cent).

Its highest correlations among both sexes were with incorrigibility, rudeness, defiant attitude, disturbing influence in school, and fighting or quarrelsomeness (including violence, undifferentiated), the boys' coefficients ranging from .36 to .48 and the girls' from .44 to .52 (Table 61). Lying, destructiveness, and violence among girls also yielded large correlations in the

Conduct prognosis bad.....	.13	.20 ± .06 (47-51)

## Other Correlations (Positive to Negative)

Temper display, .19 and .19; Leader, .18 and .15; Refusal to attend school, .17 and .12; Unhappy, .17 and .17; Hatred or jealousy of sibling, .15 and .11; Psychoneurotic, .15 and .16; Grouped: depressed, etc., .15 and .11; Inefficient in work, play, etc., .14 and .13; Crying spells, .14 and .13; Depressed, .14 and -.03; Changeable moods, .13 and .12; Preference for younger children, .13 and .01; Victim of sex abuse, .12 (girls); "Nervous," .12 and .19; Brother in penal detention, .12 and -.02; Enuresis, .11 and .12; Absent-minded, .11 and .05; Object of teasing, .11 and .17; Sensitive (general), .11 and .02; Former convulsions, .11 and .02; Inferiority feelings, .10 and .04; Poor work in school, .10 and .16; Nail-biting, .09 and .07; Discord between parents, .09 and .19; Emotional instability, .08 and .19; Grouped: dull, slow, etc., .08 and -.14; Grouped: sensitive or worrisome, .08 and .06; Sensitive over specific fact, .07 and .04; Sex denied entirely, .07 and -.05; Popular, .07 and .05; Attractive manner, .07 and .04; Seclusive, .06 and -.08; Oversuggestible, .04 and .08; Retardation in school, .04 and -.06; Neurological defect, .04 and -.03; Worry over specific fact, .03 and .13; Follower, .03 and .00; Daydreaming, .02 and .13; Stuttering, .02 (boys); Underweight, .02 and .03; Question of hypomania, .01 and .04; Headaches, .00 and .10; Irregular attendance at school, -.01 and -.16; Immoral home conditions, -.03 and -.02; Speech defect, -.03 and -.07; Repressed, -.03 and .04; Vocational guidance, -.05 and -.15; Clean, -.05 and -.06; Slow, dull, -.06 and -.13; Listless, -.07 and .03; Vicious home conditions, -.08 and .13; Apprehensive, -.08 and .06; Lack of initiative, -.10 and -.06; Bashful, -.13 and -.06; Lues, -.14 and .02; Feeble-minded sibling, -.18 and -.14

Omitted—Grouped: disobedient, etc.

.40's, with substantial coefficients among boys ranging from .29 to .31.

Three conduct problems—stubbornness, staying out late at night, and swearing or bad language (undifferentiated)—yielded substantial correlations in the .30's for both sexes. Smoking, for which only the boys' correlation was calculated, and overinterest in the opposite sex, for which only the girls' coefficient was computed, also yielded substantial correlations in the .30's. Among boys boastful or "show-off" manner and truancy from home yielded substantial correlations in the .30's and lesser coefficients of  $.20 \pm .05$  and .19 respectively among girls. Among girls ten notations yielded substantial correlations in the .30's, with corresponding moderate coefficients in the .20's among boys: sullenness, temper tantrums, leading others into bad conduct, fighting, quarrelsomeness, egocentricity, question of change of personality, inattentiveness in school, exclusion from school, and unpopularity. Overinterest in sex matters among girls also yielded the substantial correlation of  $.30 \pm .05$  but a corresponding low correlation of .09 among boys.

Disobedience showed moderate correlations in the .20's among both sexes for seven behavior traits: stealing, selfishness, irresponsibility, fantastical lying, restlessness, irregular sleep habits, and lack of interest in school. Five behavior problems, for which only the boys' correlations were calculated, also showed moderate correlations in the .20's: swearing in general, running with a gang, threatening violence, teasing other children, and complaining of bad treatment by other children. Four conduct notations among boys similarly showed moderate correlations in the .20's but low positive correlations below .20 among girls: contrariness, laziness, loitering or wandering, and sulkiness. Among girls a large list of fifteen miscellaneous notations showed moderate correlations in the .20's, but low or negligible correlations ranging from  $-.03$  to .19 among boys: sex delinquency (coitus), masturbation, excuse-forming attitude, bad companions, "spoiled child", irritable temperament, bossy manner, distractibility, slow-wittedness, restlessness in sleep, finicky food habits, mental conflict, queer behavior, question or diagnosis of encephalitis, and staff notation of unfavorable conduct prognosis.

No negative correlations of statistically significant size

were found with disobedience.

Among the six sex notations moderate to substantial correlations in the .20's to .30's were found among girls for sex delinquency (coitus), overinterest in sex matters, masturbation, and overinterest in the opposite sex (calculated for girls only). All the boys' correlations in this field were low or negligible.

Among the seven physical or psychophysical notations the only significant correlation was with question or diagnosis of encephalitis among girls,  $.29 \pm .07$ , all the other coefficients in this field being low or negligible.

Among the four home or familial notations (discord between parents, vicious or immoral home conditions, and brother in penal detention) all coefficients were low or negligible, ranging from  $-.08$  to  $.19$ .

Incorrigibility was noted among 501, or 23.7 per cent, of our boys and among 212, or 18.0 per cent, of our girls. In comparison with the other five conduct problems in this chapter, its correlations with conduct-total were unusually high, the coefficients for boys and girls respectively being  $.52 \pm .02$  and  $.59 \pm .02$  (Table 62). With the personality-total and police-arrest criteria its correlations were moderate or substantial, ranging from  $.23$  to  $.38$ .

Its highest correlations were in the .50's among girls for disobedience and swearing or bad language (undifferentiated), the corresponding boys' coefficients in the .40's also being large. The six conduct disorders—defiant attitude, rudeness, truancy from home, staying out late at night, fighting, and stealing—yielded large correlations ranging from  $.39$  to  $.49$  among both sexes. Overinterest in the opposite sex (computed for girls only) also yielded the large correlation of  $.42 \pm .04$ . Destructiveness and staff notation of unfavorable conduct prognosis among boys yielded similarly large correlations in the .40's, the girls' coefficients being lower,  $.33 \pm .06$  and  $.20 \pm .06$  respectively. Among girls, five conduct problems similarly yielded large correlations in the 40's with corresponding substantial coefficients in the .30's among boys: disturbing influence in school, truancy from school, violence, quarrelsomeness, and temper tantrums.

Six notations consistently yielded substantial correlations

## Other Correlations (Positive to Negative)

Inattentive in school, .19 and .19; Discord between parents, .18 and .03; Spoiled child, .17 and .19; Selfish, .13 and .18; Oversuggestible, .13 and .09; Lack of interest in school, .12 and .14; Overinterest in sex matters, .12 and .12; Enuresis, .11 and .17; Nail-biting, .11 and .18; Sulky, .11 and .14; Crying spells, .11 and .10; Depressed, .10 and .15; Bossy, .09 and .19; Inefficient in work, play, etc., .09 and .14; Inferiority feelings, .09 and .06; Popular, .09 and .05; Brother in penal detention, .09 and -.07; Hatred or jealousy of sibling, .08 and -.01; Sex denied entirely, .08 and -.06; Irregular attendance at school, .08 and -.12; Victim of sex abuse, .08 (girls); "Nervous," .07 and .14; Mental conflict, .07 and -.00; Question of hypochondria, .07 and .07; Restless in sleep, .06 and -.00; Poor work in school, .06 and .08; Leader, .06 and .17; Former convulsions, .05 and .04; Lazy, .04 and .08; Absent-minded, .04 and .12; Sensitive over specific fact, .04 and .09; Retardation in school, .04 and -.01; Headaches, .04 and .14; Attractive manner, .04 and -.04; Seclusive, .03 and .02; Clean, -.00 and -.07; Grouped: sensitive or worrisome, etc., -.01 and .01; Vicious home conditions, -.01 and .07; Psychoneurotic, -.01 and .02; Apprehensive, -.02 and .08; Worry over specific fact, -.04 and .03; Repressed, -.04 and -.00; Neurological defect, -.05 and -.03; Preference for younger children, -.05 and .14; Follower, -.06 and -.08; Sensitive (general), -.06 and -.06; Stuttering, -.07 (boys); Speech defect, -.08 and -.10; Underweight, -.08 and .03; Listless, -.08 and -.03; Lack of initiative, -.09 and -.14; Bashful, -.10 and -.17; Immoral home conditions, -.11 and -.01; Slow, dull, -.12 and -.10; Feeble-minded sibling, -.13 and -.15; Grouped: dull, slow, etc., -.13 and -.08; Lues, -.15 and .14

Omitted—Grouped: disobedient, etc.

in the .30's: leading others into bad conduct, lying, exclusion from school, and the three for which only the boys' coefficients were calculated—running with a gang, threatening violence, and swearing in general. Contrariness and bad companions among boys similarly yielded substantial coefficients in the .30's, with moderate coefficients in the .20's among girls. Seven conduct and personality difficulties among girls similarly yielded substantial correlations in the .30's, with moderate coefficients in the .20's among boys: stubbornness, egocentricity, boastful or "show-off" manner, excuse-forming attitude, loitering or wandering, restlessness, and emotional instability. An additional five notations also yielded substantial correlations in the .30's among girls but low coefficients below .20 among boys: temper display, irritable temperament, question of change of personality, unpopularity, and question or diagnosis of encephalitis.

Nine behavior traits uniformly showed moderate correlations with incorrigibility in the .20's: sullenness, refusal to attend school, fantastical lying, irregular sleep habits, slovenliness, unhappiness, and the three behavior problems for which only the boys' coefficients were calculated—smoking, teasing other children, and complaining of bad treatment by other children. Ten personality and conduct problems among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: sex delinquency (coitus), masturbation, irresponsibility, distractibility, changeable moods or attitudes, lack of interest or inattentiveness in school studies or employment (undifferentiated), daydreaming, queer behavior, finicky food habits, and object of teasing by other children.

The only negative correlation of significant size was with the routine notation "request for vocational guidance" among girls,  $-.21 \pm .04$ .

Among the six sex notations there were three statistically significant correlations with incorrigibility, all among girls: the large tetrachoric  $r$  of  $.42 \pm .04$  with overinterest in the opposite sex (calculated for girls only), and the moderate coefficients of  $.22 \pm .04$  with sex delinquency (coitus) and  $.23 \pm .04$  with masturbation. All other correlations in this field were low or negligible.

Among the seven physical or psychophysical notations the

only meaningful correlation was the substantial coefficient of  $.31 \pm .07$  with question or diagnosis of encephalitis among girls, all other coefficients in this field being low or negligible.

Among the four home or familial conditions all correlations were low or negligible, ranging from  $-.11$  to  $.18$ .

Defiant attitude toward parents, teachers, etc. was noted among 178, or 8.4 per cent, of the boys and among 95, or 8.0 per cent, of the girls. Its bi-serial correlations with the conduct-total,  $.43 \pm .02$  and  $.68 \pm .03$  for boys and girls respectively, and also with the personality-total for girls,  $.53 \pm .03$ , were high, while its tetrachoric correlations with police arrest and the boys' bi-serial correlation with the personality-total were only moderate or low, ranging from  $.14$  to  $.20$  (Table 63). Its correlations with disobedience, incurability, and stubbornness were large, ranging from  $.41$  to  $.49$ , and its correlation with contrariness substantial, the coefficients being  $.33$  and  $.34$ .

Its highest correlations were with rudeness, the coefficients being  $.49 \pm .03$  and  $.54 \pm .04$  for boys and girls respectively. Stealing and temper tantrums among girls also yielded high coefficients in the .50's, with substantial correlations in the .30's among boys. Its correlations with sullenness were also large,  $.41 \pm .04$  and  $.44 \pm .06$  for boys and girls respectively. Violence and egocentricity or selfishness (undifferentiated) among girls yielded large correlations in the .40's with substantial coefficients in the .30's among boys. Four undesirable behavior traits similarly yielded large correlations in the .40's for girls and moderate correlations in the .20's for boys: disturbing influence in school, fighting, lying, and selfishness.

Four conduct problems yielded substantial correlations in the .30's for both sexes: contrariness, quarrelsomeness, destructiveness, and swearing or bad language (undifferentiated). Excuse-forming attitude and exclusion from school among boys similarly yielded substantial correlations in the .30's, with moderate correlations in the .20's among girls. Among girls there were five undesirable behavior traits showing substantial correlations in the .30's and moderate correlations in the .20's among boys: leading others into bad conduct, staying out late at night, truancy from school, egocentricity, and boastful or "show-off" manner.

Nail-biting, .18 and .15; Teasing other children, .17 (boys); Popular, .17 and .12; Bossy, .16 and .19; Former convulsions, .15 and .08; Emotional instability, .14 and .18; Seclusive, .13 and .19; Complaining of bad treatment by other children, .12 (boys); Victim of sex abuse, .12 (girls); Attractive manner, .11 and .07; Crying spells, .10 and .19; Discord between parents, .07 and .06; Clean, .06 and -.02; Conduct prognosis bad, .05 and .16; Listless, .04 and .11; Enuresis, .03 and .16; Overinterest in sex matters, .03 and .16; Psychoneurotic, .03 and .09; Sensitive (general), .03 and .13; Sex delinquency (coitus), .01 and .07; Mental conflict, .01 and .14; Repressed, .01 and .04; Sex denied entirely, .00 and .07; Poor work in school, -.00 and -.01; "Nervous," -.01 and .15; Vocational guidance, -.02 and .01; Immoral home conditions, -.03 and -.04; Apprehensive, -.03 and .19; Brother in penal detention, -.04 and -.09; Oversuggestible, -.04 and .06; Slow, dull, -.04 and -.06; Grouped: dull, slow, etc., -.05 and

TABLE 63—Continued

-.01; Lack of initiative, -.05 and .05; Lues, -.06 and .04; Neurological defect, -.06 and .08; Absent-minded, -.06 and .01; Stuttering, -.08 (boys); Vicious home conditions, -.09 and .11; Speech defect, -.09 and .04; Irregular attendance at school, -.09 and -.13; Headaches, -.09 and .11; Preference for younger children, -.09 and .11; Bashful, -.09 and .06; Underweight, -.13 and -.01; Question of hypochondria, -.14 and -.11; Retardation in school, -.17 and -.17  
Omitted—Grouped: disobedient, etc.

Nine additional behavior problems among girls yielded substantial correlations in the .30's, but low correlations below .20 among boys: refusal to attend school, "spoiled child," finicky food habits, inefficiency in work, play, etc., restlessness in sleep, question of change of personality, depressed mood or spells, day-dreaming, and queer behavior.

Sulkiness, truancy from home, and lack of interest or inattentiveness in school studies or employment (undifferentiated) showed moderate correlations in the .20's among both sexes with defiant attitude. Three behavior problems, for which only the boys' correlations were calculated, also showed only moderate correlations in the .20's: running with a gang, threatening violence, and smoking. Overinterest in the opposite sex (calculated for girls only) similarly showed the moderate correlation of .23 + .05. Hatred or jealousy of sibling among boys showed the moderate correlation of .21 + .06 but a corresponding low coefficient of .16 among girls. A large list of twenty-three miscellaneous notations among girls showed moderate correlations in the .20's but low coefficients ranging from -.05 to .19 among boys: bad companions, temper display, irritable temperament, loitering or wandering, fantastical lying, laziness, slovenliness, lack of interest in school, irresponsibility, restlessness, distractibility, irregular sleep habits, changeable moods or attitudes, sensitiveness or worrisomeness (undifferentiated), sensitiveness over some specific fact, worry over some specific fact, inferiority feelings, unhappiness, unpopularity, object of teasing by other children, masturbation, "leader," and question or diagnosis of encephalitis.

Two notations showed negative correlations among both sexes, -.32 + .06 for feeble-minded sibling and -.25 + .06 for "follower" among girls, the corresponding boys' coefficients being low, -.19 and -.12 respectively.

Among the six sex notations defiant attitude showed moderate correlations among the girls with masturbation,  $.29 \pm .05$ , and with overinterest in the opposite sex,  $.23 \pm .05$  (calculated for girls only). All other correlations in this field were negligible.

Among the seven physical or psychophysical notations the only significant correlation was the moderate one of  $.25 \pm .08$  with question or diagnosis of encephalitis among girls. All other correlations in this field were low or negligible.

Among the four home or familial notations all correlations were negligible, ranging from  $-.09$  to  $.11$ .

Stubbornness was noted among 420 boys, or 19.9 per cent, and among 220 girls, or 18.6 per cent. Its bi-serial correlations with conduct-total and personality-total were generally substantial, the coefficients ranging from  $.25$  to  $.43$  (Table 64). Its correlations of  $.08$  and  $.09$  with the police-arrest criterion of "juvenile delinquency" were quite negligible. Its correlations with defiant attitude were fairly large,  $.42 \pm .03$  and  $.44 \pm .04$ , while its correlations with disobedience, incorrigibility, and contrariness were only moderate or substantial, ranging from  $.21$  to  $.37$ .

Its largest correlations among both sexes thus were with defiant attitude. Among girls large correlations in the  $.40$ 's were found for temper tantrums and depressed mood or spells, the corresponding boys' coefficients being definitely lower,  $.23 \pm .03$  and  $.14$  respectively.

The three conduct problems—disobedience, sullenness, and (calculated for boys only) smoking—yielded substantial correlations in the  $.30$  s. Contrariness among boys yielded the substantial correlation of  $.33 \pm .04$ , with a corresponding moderate correlation of  $.22 \pm .06$  among girls. Six conduct problems among girls yielded substantial correlations in the  $.30$ 's, with moderate correlations in the  $.20$ 's among boys: incorrigibility, disturbing influence in school, violence, temper display, rudeness, and "nervousness" or restlessness (including irritable temperament and changeable moods or attitudes, undifferentiated). In addition, five undesirable behavior traits among girls yielded substantial correlations in the  $.30$ 's but low positive correlations below  $.20$  among boys: selfishness, egocentricity, lying, hatred or jealousy

## Other Correlations (Positive to Negative)

Absent-minded, .19 and .09; Threatening violence, .18 (boys); Teasing other children, .17 (boys); Seclusive, .17 and .17; "Nervous," .16 and .13; Leader, .15 and .12; Grouped: sensitive or worrisome, etc., .15 and .19; Restless in sleep, .15 and .19; Victim of sex abuse, .15 (girls); Slovenly, .14 and .17; Complaining of bad treatment by other children, .13 (boys); Unhappy, .13 and .07; Headaches, .13 and .01; Discord between parents, .12 and .08; Crying spells, .12 and .15; Bashful, .12 and -.03; Truancy from school, .11 and .18; Lack of initiative, .11 and -.02; Object of teasing, .11 and .12; Conduct prognosis bad, .11 and .10; Preference for younger children, .11 and -.04; Question of encephalitis, .10 and .13; Former convulsions, .10 and -.06; Emotional instability, .10 and .15; Inferiority feelings, .10 and .07; Nail-biting, .10 and .09; Attractive manner, .09 and -.09; Loitering, .09 and .02; Oversuggestible, .09 and .02; Neurological defect, .08 and .09; Lack of interest in school, .08 and .16; Gang, .07 (boys); Sensitive (general), .07 and .17; Popular, .07 and .02; Grouped: dull, slow, etc., .07 and -.02; Vocational guidance, .06 and .11; Repressed, .06 and .02; Bad companions, .05 and .18; Irresponsible, .05 and .12; Slow, dull, .05 and -.04; Clean, .04 and .12; Follower, .04 and -.11; Immoral home conditions, .03 and .10; Apprehensive, .01 and -.01; Sex denied entirely, .01 and .11; Poor work in school, .01 and -.06; Psychoneurotic, -.00 and .16; Listless, -.01 and .17; Speech defect, -.02 and -.06; Brother in penal detention, -.03 and -.18; Lues, -.07 and -.00; Underweight, -.07 and -.01; Stuttering, -.07 (boys); Question of hypophrenia, -.07 and -.08; Overinterest in sex matters, -.07 and .19; Irregular attendance at school, -.08 and -.08; Sex delinquency (ocituz), -.09 and .12; Retardation in school, -.11 and -.06; Vicious home conditions, -.11 and .11

Omitted—Grouped: disobedient, etc.

of sibling, and distractibility.

Nine behavior traits showed correlations in the .20's with stubbornness among both sexes: fighting, quarrelsomeness, swearing or bad language (undifferentiated), bossy manner, sulkiness, "spoiled child," queer behavior, inefficiency in work, play, etc., and daydreaming. Overinterest in the opposite sex, which was calculated for girls only, also showed a moderate correlation of .29 + .04. Three additional traits—refusal to attend school, irritable temperament, and irregular sleep habits—among boys yielded moderate correlations in the .20's but low positive correlations below .20 for girls. A large list of twenty-one miscellaneous notations among girls showed moderate correlations in the .20's but low correlations below .20 for the boys: stealing, truancy from home, staying out late at night, leading others into bad conduct, excuse-forming attitude, fantastical lying, boastful or "show-off" manner, destructiveness, laziness, restlessness, mental conflict, question of change of personality, changeable moods or attitudes, sensitiveness over some specific fact, worry over some specific fact, unpopularity, inattentiveness in school, exclusion from school, masturbation, finicky food habits, and enuresis.

Feeble-minded sibling showed low or moderate negative correlations of  $-.15$  and  $-.24 + .05$  among boys and girls respectively.

Among the six sex notations there were two coefficients of moderate size, both among girls: masturbation,  $.26 + .04$ , and (calculated for girls only) overinterest in the opposite sex,  $.29 + .04$ , the other coefficients in this field being low or negligible.

Among the seven physical or psychophysical notations there was one coefficient of moderate size, enuresis among girls,  $.23 + .04$ , the remaining coefficients in this field being negligible, ranging from  $-.07$  to  $.13$ .

The four home or familial notations showed only low or negligible correlations with stubbornness.

The notation contrariness, negativism, resistiveness, antagonistic attitude, etc., was noted among 4.2 per cent of our boys and among 4.3 per cent of our girls. Its correlations with the personality-total and conduct-total were large (especially among boys), its bi-serial correlations ranging from  $.34$  to  $.48$  (Table 65

TABLE 65

## Other Correlations (Positive to Negative)

Lying, .19 and .11; Truancy from school, .19 and -.01; Distractible, .19 and .00; Inefficient in work, play, etc., .18 and .05; "Nervous," .18 and .17; Nail-biting, .17 and -.09; Irresponsible, .16 and .13; Emotional instability, .16 and .08; Irregular attendance at school, .16 and -.02; Neurological defect, .16 and .09; Overinterest in sex matters, .15 and -.13; Apprehensive, .15 and .08; Irregular sleep habits, .15 and .16; Bossy, .14 and .18; Staying out late at night, .13 and .11; Restless in sleep, .13 and .11; Attractive manner, .13 and .04; Masturbation, .12 and .10; Crying spells, .12 and .12; Mental conflict, .12 and .01; Teasing other children, .11 (boys); Enuresis, .10 and -.03; Inattentive in school, .09 and .03; Worry over specific fact, .09 and .03; Poor work in school, .09 and .01; Leader, .09 and .04; Sex denied entirely, .08 and .09; Headaches, .08 and .08; Discord between parents, .08 and -.07; Loitering, .06 and .10; Grouped: sensitive or worrisome, etc., .06 and .12; Sensitive over specific fact, .05 and .01; Clean, .04 and .10; Underweight, .03 and -.09; Bad companions, .03 and .01; Psychoneurotic, .02 and .09; Vicious home conditions, .02 and .00; Sex delinquency (coitus), .00 and .07; Former convulsions, -.02 and -.03; Question of hypophrenia, -.02 and -.01; Oversuggestible, -.02 and -.11; Lack of initiative, -.02 and .03; Brother in penal detention, -.03 and -.09; Grouped: dull, slow, etc., -.05 and .06; Follower, -.05 and -.18; Bashful, -.05 and -.09; Vocational guidance, -.07 and -.04; Popular, -.07 and .11; Slow, dull, -.10 and -.07; Stuttering, -.11 (boys); Retardation in school, -.13 and -.13; Lues, -.16 and .13; Victim of sex abuse, -.18 (girls); Immoral home conditions, -.18 and -.02; Feeble-minded sibling, -.18 and -.09

Omitted—Grouped: disobedient, etc.

Its tetrachoric correlations with police arrest among boys was moderate,  $.27 \pm .04$ , but negligible among girls. Its correlations with the other four similar traits—disobedience, incurrigibility, defiant attitude, and stubbornness—were generally substantial, ranging from  $.16$  to  $.39$ .

The highest correlations were in the .40's. Rudeness yielded correlations of  $.42 \pm .04$  and  $.32 \pm .06$  for boys and girls respectively. Destructiveness yielded corresponding correlations of  $.37 \pm .04$  and  $.46 \pm .08$ . Leading others into bad conduct among girls yielded the large correlation of  $.41 \pm .09$  but a corresponding low coefficient of  $.08$  among boys.

Four conduct problems yielded substantial correlations in the .30's for both sexes: sullenness, swearing or bad language (undifferentiated), defiant attitude, and temper tantrums or display (undifferentiated). Four undesirable behavior traits among boys yielded substantial correlations in the .30's, with corresponding moderate coefficients in the .20's among girls: stubbornness, egocentricity, incurrigibility, and "nervousness" or restlessness (including irritable temperament and changeable moods or attitudes, undifferentiated). Four additional behavior traits among boys similarly yielded substantial correlations in the .30's but low coefficients below  $.20$  among girls: selfishness, disturbing influence in school, hatred or jealousy of sibling, and question of change of personality. Among girls four behavior traits yielded substantial correlations in the .30's, with moderate coefficients in the .20's among boys: sulkiness, changeable moods or attitudes, irritable temperament, and violence. Three additional behavior traits among girls yielded substantial correlations in the .30's but low positive coefficients below  $.20$  among boys: unhappiness, listlessness, and repressed manner.

Seven conduct and personality traits showed moderate correlations in the .20's with contrariness among both sexes: temper tantrums, temper display, fighting, boastful or "show-off" manner, queer behavior, seclusiveness, and daydreaming. Five behavior traits, for which only the boys' correlations were computed because of the paucity of girls' cases, also showed moderate correlations in the .20's: running with a gang, threatening violence, swearing in general, smoking, and complaining of bad treatment by other children. Overinterest in the opposite sex (calculated for girls

only) likewise showed the moderate correlation of  $.21 \pm .06$ . Thirteen miscellaneous notations among boys showed moderate correlations in the .20's but low coefficients below .20 among girls: disobedience, refusal to attend school, "spoiled child," truancy from home, quarrelsomeness, fantastical lying, exclusion from school, unpopularity, restlessness, slovenliness, absent-mindedness, staff notation of unfavorable conduct prognosis, and question or diagnosis of encephalitis. Eight behavior problems among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: stealing, laziness, excuse-forming attitude, lack of interest in school, finicky food habits, sensitiveness in general, depressed mood or spells, and object of teasing by other children.

Contrariness showed two negative correlations of moderate size in the -.20's: speech defect among boys and preference for younger children as playmates among girls, the other two coefficients being quite negligible in size.

Among the six sex notations the only coefficient of moderate size was with overinterest in the opposite sex,  $.21 \pm .06$  among girls, the boys' coefficient not being computed because of paucity of cases.

Among the seven physical or psychophysical notations there were two correlations of moderate size both among boys:  $.29 \pm .07$  with question or diagnosis of encephalitis and the negative coefficient of  $-.22 \pm .06$  with speech defect (other than stuttering).

Among the four home or familial notations all correlations with contrariness were low or negligible.

When the cases falling under the five rubrics, disobedience, incurability, defiant attitude, stubbornness, and contrariness, were combined into one broad grouping,<sup>1</sup> there were 992 such cases, or 46.9 per cent, among our 2,113 White boys and 482 cases, or 40.8 per cent, of our 1,181 White girls. These conduct problems thus provided the most frequently appearing behavior notations among our clinic cases. The resulting correlation coefficients (Table 66) were so similar to those for the five component

<sup>1</sup>The reasons for this broader grouping were given in I, 44; see 86, Table 13, Item B.

Omitted—Contrary; Defiant; Disobedient; Stubborn; Incurable

notations, though generally slightly larger, that only a brief summary is necessary.

The following nine conduct problems consistently yielded large or high correlations with the larger grouping disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), ranging from the .40's to the .60's: rudeness, violence, staying out late at night, sullenness, disturbing influence in school, swearing or bad language (undifferentiated), truancy from home, stealing, and (calculated for girls only) overinterest in the opposite sex. Seven additional conduct notations among girls yielded large correlations ranging from .40 to .53, with moderate to substantial coefficients ranging from .23 to .39 for boys: lying, fighting, quarrelsomeness, temper tantrums, temper display, leading others into bad conduct, and excuse-forming attitude. A large list of twenty-five behavior notations showed moderate to substantial correlations ranging from .17 to .40 among both sexes: bad companions, running with a gang (calculated for boys only), refusal to attend school, threatening violence (calculated for boys only), destructiveness, boastful or "show-off" manner, truancy from school, exclusion from school, smoking (calculated for boys only), "spoiled child," hatred or jealousy of sibling, egocentricity, selfishness, irritable temperament, sulkiness, loitering or wandering, irresponsibility, inefficiency in work, play, etc., restlessness, queer behavior, changeable moods or attitudes, question of change of personality, unpopularity, unhappiness, and staff notation of unfavorable conduct prognosis.

Among the six sex notations the following four showed coefficients of significant size, all among girls: overinterest in the opposite sex (calculated for girls only),  $.40 \pm .03$ , sex delinquency (coitus),  $.27 \pm .03$ , overinterest in sex matters,  $.23 \pm .05$ , and masturbation,  $.26 \pm .04$ .

Among the seven physical or psychophysical notations there

were two correlations of moderate size in the .20's, both among girls: enuresis and question or diagnosis of encephalitis.

Among the home or familial notations all correlations were low, ranging from -.11 to .15.

We may summarize the more interesting correlations for all five notations, disobedience, incurrigibility, defiant attitude, stubbornness, and contrariness (Tables 61-65, inclusive), as follows. The largest correlations, ranging from .20's to the .50's, were found for the following thirteen behavior notations: rudeness, sullenness, violence, disturbing influence in school, fighting, swearing or bad language (undifferentiated), threatening violence (calculated for boys only), stealing, overinterest in the opposite sex (calculated for girls only), temper tantrums, smoking (calculated for boys only), egocentricity, and boastful or "show-off" manner. Another group of fifteen notations showed many substantial or large correlations but not uniformly for all five traits or for both sexes: staying out late at night, leading others into bad conduct, running with a gang (calculated for boys only), truancy from home, quarrelsomeness, irritable temperament, lying, selfishness, "spoiled child", finicky food habits, queer behavior, question of change of personality, unpopularity, exclusion from school, and question or diagnosis of encephalitis.

Among the six sex notations all five traits considered in this chapter showed moderate or substantial correlations, ranging from .21 to .42, with overinterest in the opposite sex, for which only the girls' correlations were calculated. Masturbation among girls showed moderate correlations in the .20's for all these notations except contrariness. Sex delinquency (coitus) among girls showed moderate correlations in the .20's with disobedience and incurrigibility. The remaining correlations for girls and all coefficients for boys in the sex sphere were low or negligible.

Among the seven physical or psychophysical notations question or diagnosis of encephalitis among girls showed moderate correlations, ranging from .25 to .31, with disobedience, incurrigibility, and defiant attitude and among boys with contrariness. Among boys enuresis showed moderate correlations of  $.23 \pm .04$  with stubbornness. Speech defect (other than stuttering) among boys showed the moderate negative coefficient of  $-.22 \pm .06$  with contra-

riness. The remaining coefficients in this field were low or negligible.

Among the four home or familial notations all the forty correlation coefficients were low or negligible.

## CHAPTER XXXVII

### LYING, PROTECTIVE AND FANTASTICAL

Lying or marked untruthfulness<sup>1</sup> (generally "protective" in purpose) was noted among 637 cases, or 30.1 per cent, of our 2,113 White boys and among 340 cases, or 28.8 per cent, of our 1,181 White girls and was thus one of the most frequently occurring conduct problems in our data. Its bi-serial correlations of  $.48 \pm .02$  and  $.56 \pm .02$  with the conduct-total among boys and girls respectively indicates a high relationship with behavior problems in the conduct sphere (Table 67). With police arrest and personality-total its correlations were of substantial size in the .30's among girls and of moderate size in the .20's among boys. Its correlations with intelligence quotient (IQ) in the data of the present volume were negligible (Table 10, p. 130) but among younger or pre-adolescent children its correlations with IQ were of moderate size,  $.24 \pm .02$  and  $.27 \pm .03$  for boys and girls respectively.<sup>2</sup>

Among both sexes its highest correlations were with stealing and fantastical lying, the tetrachoric correlations ranging from .56 to .68. Among girls the two notations, unpopularity and disobedience or incorrigibility (undifferentiated), also yielded large coefficients in the .50's, with corresponding coefficients among boys of substantial size in the .30's.

Four conduct problems yielded large correlations in the .40's: truancy from home and truancy from school, among both sexes, and smoking (calculated for boys only) and overinterest in

---

<sup>1</sup>In the original indexing of 5,000 cases, separate categories were included for question of making false accusations (I, 61, Table 3, Item 222); question of pathological lying, i.e., derogatory to self (*ibid.*, Item 252); lying to police or school official, etc., re identity, address, etc., or assuming false name, address, disguise, etc. (*ibid.*, Item 264); question of pathological accusation, i.e., inculpating self (*ibid.*, Item 289); and lying concerning age to person with whom patient was sexually delinquent or to whom patient was engaged (*ibid.*, Item 300); but these interesting notations were of too infrequent incidence to warrant separate correlational analysis.

<sup>2</sup>I, 175-77.

## Other Correlations (Positive to Negative)

Contrary, .19 and .11; Nail-biting, .19 and .18; Unhappy, .19 and .15; Lazy, .18 and .13; Irregular sleep habits, .18 and .16; Spoiled child, .18 and .17; Irregular attendance at school, .18 and .07; Hatred or jealousy of sibling, .17 and .15; Irritable, .16 and .11; Former convulsions, .15 and -.08; Vicious home conditions, .14 and .17; Enuresis, .13 and .19; Repressed, .13 and .05; Brother in penal detention, .13 and -.03; Discord between parents, .13 and .19; Grouped: depressed, etc., .13 and .16; Refusal to attend school, .12 and .16; Follower, .11 and .08; Grouped: sensitive or worrisome, etc., .10 and .18; Crying spells, .09 and .16; Object of teasing, .09 and .18; Popular, .08 and .02; Absent-minded, .07 and .14; Depressed, .07 and .14; Preference for younger children, .07 and .16; Attractive manner, .07 and .13; "Nervous," .06 and .19; Headaches, .06 and .19; Immoral home conditions, .06 and .13; Finicky good habits, .05 and .12; Seclusive, .05 and .05; Sensitive (general), .05 and .01; Worry over specific fact, .05 and .12; Poor work in school, .04 and .04; Sex denied entirely, .02 and .07; Clean, -.00 and -.00; Apprehensive, -.01 and .12; Lies, -.02 and .02; Speech defect, -.03 and -.10; Slow, dull, -.03 and -.05; Neurological defect, -.04 and .09; Grouped: dull, slow, etc., -.06 and -.02; Under-

TABLE 67—Continued

weight, -.06 and -.02; Stuttering, -.06 (boys); Question of hypophrenia, -.06 and -.08; Lack of initiative, -.06 and -.02; Bashful, -.06 and -.09; Listless, -.07 and .02; Retardation in school, -.08 and -.11; Psychoneurotic, -.08 and .04; Changeable moods, -.12 and .18; Feeble-minded sibling, -.18 and -.11

the opposite sex (calculated for girls only). Among girls four conduct problems similarly yielded large correlations in the .40's, with substantial coefficients of .30 or .31 among boys: disobedience, disturbing influence in school, fighting, and swearing or bad language (undifferentiated). Five additional behavior notations among girls similarly yielded large correlations in the .40's but moderate coefficients in the .20's among boys: defiant attitude, violence, irresponsibility, exclusion from school, and overinterest in sex matters.

Eleven undesirable behavior manifestations yielded substantial correlations, ranging from .27 to .39, among both sexes: boastful or "show-off" manner, excuse-forming attitude, egocentricity, rudeness, incorrigibility, staying out late at night, loitering or wandering, bad companions, leading others into bad conduct, destructiveness, and masturbation. Among girls six additional traits yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: stubbornness, quarrelsomeness, inefficiency in work, play, etc., queer behavior, daydreaming, and sex delinquency (coitus).

Lying yielded moderate correlations in the .20's with thirteen behavior problems: sullenness, bossy manner, temper tantrums, slovenliness, inattentiveness in school, mental conflict, inferiority feelings, staff notation of unfavorable conduct prognosis, and the four notations for which only the boys' correlations were computed—running with a gang, threatening violence, teasing other children, complaining of bad treatment by other children, and victim of sex abuse by older child or person, which was computed for girls only. Oversuggestibility similarly showed the moderate correlation of .21 ± .03 among boys but a low correlation of .12 among girls. Twelve behavior problems among girls showed moderate correlations in the .20's but low coefficients below .20 among boys: selfishness, sulkiness, temper display, restlessness, restlessness in sleep, distractibility, staff notation of emotional instability,

lack of interest in school, sensitiveness over some specific fact, question of change of personality, "leader," and question or diagnosis of encephalitis.

The only negative correlation of significant size was with "request for vocational guidance" among girls,  $-.31 \pm .04$ .

Among the six sex problems there was a tendency toward substantial correlations with lying among both sexes. Masturbation yielded coefficients of  $.35 \pm .02$  and  $.39 \pm .04$  for boys and girls respectively. Overinterest in sex matters among girls yielded the fairly large correlation of  $.43 \pm .04$ , with a moderate correlation of  $.24 \pm .04$  among boys. Sex delinquency (coitus) among girls yielded the substantial correlation of  $.33 \pm .03$  and a low positive coefficient of  $.15$  among boys. Among girls overinterest in the opposite sex and victim of sex abuse by older child or person yielded the substantial correlations of  $.40 \pm .04$  and  $.29 \pm .04$  respectively, the boys' coefficients not being computed because of paucity of cases. Sex misbehavior denied entirely showed the negligible coefficients of  $.02$  and  $.07$ .

Among the seven physical or psychophysical notations all correlations were low or negligible, except two coefficients among girls,  $.27 \pm .06$  with question or diagnosis of encephalitis and  $.19$  with enuresis (continued beyond third birthday).

Among the four home or familial notations all correlations with lying tended to be positive but low, ranging from  $-.03$  to  $.19$ .

Fantastical lying in our data was rigidly defined as the telling of imaginative false stories for the purpose of either glorifying the narrator or of attracting the favorable attention of the listener. It did not include "pathological lying and accusation," which in our data was defined to include only cases in which the apparent purpose of the child's false assertions seemed to be derogatory to himself. Fantastical lying was noted among 104, or 4.9 per cent, of our boys and among 75, or 6.4 per cent, of our girls. Its large bi-serial correlations in the .40's with the conduct-total indicate its meaningful relation with conduct disorders (Table 68), and its almost equally large correlations with the personality-total suggests that fantastical lying is a greater indicator of personality deviation than "protective" lying, in which we have previously noted that the correlations were only

habits, .01 and .19; Brother in penal detention, .01 and -.13; Sensitive over specific fact, -.01 and .12; Psychoneurotic, -.01 and .19; Listless, -.01 and .02; Apprehensive, -.02 and .08; Grouped: dull, slow, etc., -.03 and -.01; Bashful, -.03 and -.03; Slow, dull, -.04 and -.03; Underweight, -.07 and .02; Follower, -.09 and -.03; Lack of initiative, -.09 and .11; Retardation in school, -.09 and -.10; Lues, -.13 and .07; Sex denied entirely, -.19 and -.00

moderate to substantial. Its moderate tetrachoric correlations of  $.31 \pm .04$  and  $.22 \pm .06$  among boys and girls respectively with police arrest were of about the same magnitude as those for "protective" lying. In general, lying and fantastical lying showed similar correlations with other notations with, however, a few exceptions.

The highest correlations for fantastical lying were with (protective) lying, the coefficients being  $.56 \pm .03$  and  $.61 \pm .04$ . Among boys boastful or "show-off" manner yielded the high correlation of  $.52 \pm .03$ , with a substantial coefficient of  $.37 \pm .07$  among girls. Truancy from home yielded large correlations of  $.38 \pm .04$  among boys and  $.40 \pm .05$  among girls. Among girls changeable moods or attitudes and hatred or jealousy of sibling also yielded large correlations in the .40's, with moderate or low coefficients of  $.22 \pm .03$  and .16 respectively for the boys.

Seven conduct and personality difficulties yielded substantial correlations ranging from .29 to .39 with fantastical lying among both sexes: daydreaming, "spoiled child," unpopularity, stealing, truancy from school, disturbing influence in school, overinterest in sex matters, and also one calculated for girls only, overinterest in the opposite sex. Among boys loitering or wandering and irregular sleep habits also yielded substantial correlations in the .30's, with lesser coefficients of  $.21 \pm .08$  and -.01 among girls. Among girls six behavior problems yielded substantial correlations in the .30's, with corresponding moderate coefficients in the .20's among boys: egocentricity, emotional instability, swearing or bad language (undifferentiated), truancy from school, leading others into bad conduct, and overinterest in sex matters. An additional six traits among girls also yielded substantial correlations in the .30's but low positive correlations below .20 among boys: queer behavior, question of change of personality, crying spells, restlessness in sleep, violence, and "leader "

With fantastical lying there were fourteen behavior problems showing moderate correlations in the .20's: bossy manner, irritable temperament, temper tantrums or display (undifferentiated), fighting, sullenness, restlessness, rudeness, irresponsibility, disobedience, incorrigibility, staying out late at night, and the three behavior problems for which only the boys' correlations were calculated—running with a gang, smoking, and complaining of bad treatment by other children. Among boys five behavior problems showed moderate correlations in the .20's but low positive coefficients below .20 among girls: excuse-forming attitude, contrariness, "nervousness," nail-biting, and masturbation. A large list of nineteen miscellaneous notations among girls showed moderate correlations in the .20's but low coefficients below .20 for boys: selfishness, defiant attitude, stubbornness, sulkiness, slovenliness, distractibility, inefficiency in work, play, etc., inattentiveness in school, exclusion from school, quarrelsomeness, temper display, temper tantrums, bad companions, mental conflict, sensitiveness in general, depressed moods or spells, object of teasing by other children, staff notation of unfavorable conduct prognosis, and headaches.

Two negative correlations of significant size were found, both among girls:  $-.27 \pm .06$  with feeble-minded sibling and  $-.44 \pm .05$  with "request for vocational guidance."

Among the six sex notations moderate to substantial correlations ranging from .25 to .35 were found for overinterest in sex matters among boys and girls, masturbation among boys, and overinterest in the opposite sex (calculated only for girls).

In the fields of physical disabilities and home or familial handicaps all correlations with fantastical lying were low or negligible.

## CHAPTER XXXVIII

### FIGHTING; QUARRELSOMENESS; VIOLENCE; THREATENING

The four similar conduct problems—fighting, quarrelsomeness, violence, and threatening violence—in our data were distinguished briefly as follows. Fighting implies physical combat with one or more adversaries of similar or equal prowess. Quarrelsomeness implies verbal rather than physical conflict. Violence includes striking, kicking, or otherwise injuring another person without regard for any ethical formalities which more or less surround fighting. That these three are closely related is shown by the fact that their intercorrelations tend to be higher than their correlations with other traits, the boys' intercorrelations ranging from .41 to .45 and the girls' intercorrelations from .49 to .61. Their bi-serial correlations with conduct-total, ranging from .34 to .54 among boys and from .46 to .79 among girls, shows their importance as indicators of conduct disorder. With overt juvenile delinquency their importance was only moderate, the tetrachoric correlations with police arrest ranging from .08 to .29. Among girls their correlations with personality-total were large or high, the bi-serial  $r$ 's ranging from .43 to .64; but among boys this relation was moderate, the coefficients ranging from .18 to .31.

Fighting was noted among 291 of our 2,113 White boys, or 13.8 per cent, and among 89 of our 1,181 White girls, or 7.5 per cent. It was more rarely noted among girls, but its presence among girls indicated a more serious extent of deviation in both the conduct and the personality fields.

Its largest correlations were with violence, the tetrachoric  $r$ 's for boys and girls being  $.43 \pm .03$  and  $.61 \pm .05$  respectively (Table 69). Among girls swearing or bad language (undifferentiated) and "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated) yielded high correlations of  $.54 \pm .03$  and  $.56 \pm .04$  respectively, with the considerable coefficients among boys of  $.35 \pm .03$  and  $.24 \pm .03$ .

## Other Correlations (Positive to Negative)

Bad companions, .19 and .17; Slovenly, .18 and .17; Sulky, .17 and .09; Enuresis, .13 and .19; Leader, .13 and -.07; Discord between parents, .13 and .09; Crying spells, .12 and .13; Former convulsions, .12 and .04; Hatred or jealousy of sibling, .11 and .18; Popular, .11 and .12; Lazy, .10 and .09; Depressed, .09 and .12; Sex delinquency (coitus), .08 and .09; Brother in penal detention, .08 and -.03; Absent-minded, .08 and .17; Oversuggestible, .08 and .03; Spoiled child, .08 and .18; Grouped: depressed, etc., .08 and .18; Overinterest in sex matters, .07 and .14; Inefficient in work, play, etc., .06 and .09; Poor work in school, .06 and .06; Headaches, .05 and .09; Sex denied entirely, .04 and .09; Listless, .03 and .16; Daydreaming, .02 and .16; Sensitive (general), .02 and .09; Retardation in school, .01 and -.05; Psychoneurotic, .00 and -.04; Feeble-minded sibling, -.00 and -.09; Follower, -.00 and -.07; Victim of sex abuse, -.01 (girls); Worry over specific fact, -.01 and .10; Unhappy, -.01 and .19; Apprehensive, -.01 and .06; Neurological defect, -.02 and .04; Question of hypochondria, -.02 and -.06; Grouped: sensitive or worrisome, etc., -.03 and .15; Stuttering, -.05 (boys); Sensitive over specific fact, -.05 and .11; Lack of initiative, -.05 and .02; Vocational guidance, -.06 and -.04; Lues, -.06 and .10; Grouped: dull, slow, etc., -.07 and .12; Attractive manner, -.07 and .02; Seclusive, -.07 and -.11; Underweight, -.08 and -.03; Clean, -.08 and .12; Slow, dull, -.08 and .05; Irregular attendance at school, -.09 and .03; Bashful, -.12 and -.11; Vicious home conditions, -.13 and -.01; Immoral home conditions, -.17 and .12

Omitted—Grouped: fighting, etc.

Quarrelsomeness and incorrigibility yielded large correlations in the .40's among both sexes. Five conduct problems among girls yielded large correlations in the .40's, with corresponding substantial coefficients in the .30's among boys: temper tantrums, destructiveness, disturbing influence in school, rudeness, and lying. Six additional notations among girls yielded large correlations in the .40's, the boys' coefficients being moderate, ranging from .15 to .28: defiant attitude, object of teasing by other children, excuse-forming attitude, restlessness, stealing, and exclusion from school.

Temper display yielded the substantial correlations of .34 + .03 and .30 + .04 with fighting among boys and girls respectively. Three behavior problems—boastful or "show-off" manner, truancy from school, and unpopularity—among boys yielded substantial correlations in the .30's, with moderate coefficients in the .20's among girls. Five undesirable behavior traits among girls yielded substantial correlations in the .30's, with corresponding moderate coefficients in the .20's among boys: irritable temperament, bossy manner, leading others into bad conduct, disobedience, and truancy from home. Six behavior difficulties among girls yielded substantial correlations in the .30's but low coefficients below .20 among boys: "nervousness", changeable moods or attitudes, question of change of personality, irresponsibility, queer behavior, and lack of interest in school.

Fighting showed moderate correlations in the .20's for five behavior traits—egocentricity, contrariness, stubbornness, fantastical lying, and emotional instability—among both sexes and also for the five conduct problems for which only the boys' correlations were computed: threatening violence, running with a gang, smoking, teasing other children, and complaining of bad treatment by other children and also for overinterest in the opposite sex, for which only the girls' correlations were computed. Six undesirable traits among boys showed moderate correlations in the .20's but low positive correlations below .20 among girls: refusal to attend school, staying out late at night, loitering or wandering, inattentiveness in school, staff notation of unfavorable conduct prognosis, and irregular sleep habits. Thirteen miscellaneous notations among girls showed moderate correlations in the .20's but low correlations below .20 among boys: sullenness, repressed manner, mental conflict,

inferiority feelings, restlessness in sleep, nail-biting, finicky food habits, distractibility, selfishness, preference for younger children as playmates, masturbation, question or diagnosis of encephalitis, and speech defect (other than stuttering).

Among the six sex notations two moderate correlations in the .20's were found: masturbation among girls and overinterest in the opposite sex (calculated only for girls).

Among the seven physical or psychophysical notations there were two correlations of moderate size in the .20's, both among girls, question or diagnosis of encephalitis and speech defect (other than stuttering).

Among the four home or familial notations all correlations with fighting were low, ranging from -.17 to .13.

Quarrelsomeness was noted among 292, or 13.8 per cent, of the boys and among 186, or 15.7 per cent, of the girls. Its highest correlations among both sexes were with violence, the respective correlations for boys and girls being  $.45 \pm .03$  and  $.50 \pm .04$  (Table 70). Its next highest correlation was among girls for unpopularity with a correlation of  $.52 \pm .05$ , the boys' coefficient also being substantial,  $.36 \pm .04$ . Fighting yielded large correlations in the .40's for both sexes. Boastful or "show-off" manner among boys yielded a large correlation of  $.41 \pm .03$ , the girls' coefficient being moderate,  $.27 \pm .05$ . Among girls six undesirable behavior traits also yielded large correlations in the .40's, with moderate or substantial coefficients ranging from .22 to .34 among boys: incurrigibility, egocentricity, rudeness, excuse-forming attitude, swearing or bad language (undifferentiated), and "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated).

Four conduct problems yielded substantial correlations in the .30's with quarrelsomeness among both sexes: bossy manner, temper tantrums, disturbing influence in school, defiant attitude, and also one calculated for boys only, teasing other children. Among girls seven undesirable behavior traits yielded substantial correlations in the .30's, with moderate correlations in the .20's among boys: temper display, irritable temperament, sullenness, disobedience, destructiveness, hatred or jealousy of sibling, and queer behavior. Among girls an additional five behavior difficul-

## Other Correlations (Positive to Negative)

Question of encephalitis, .19 and .14; Bad companions, .18 and .09; Lazy, .17 and .14; Overinterest in sex matters, .17 and .15; Question of change of personality, .17 and .16; Lack of interest in school, .16 and .14; Loitering, .16 and .07; Mental conflict, .15 and .18; Seclusive, .14 and .03; Overinterest in opposite sex, .13 (girls); Smoking, .12 (boys); Truancy from home, .12 and .03; Neurological defect, .12 and .00; Victim of sex abuse, .12 (girls); Staying out late at night, .11 and .15; Masturbation, .11 and .18; Psychoneurotic, .11 and .14; Preference for younger children, .11 and .12; Unhappy, .11 and .19; Vocational guidance, .11 and -.08; Object of teasing, .10 and .13; Sensitive (general), .10 and .18; Spoiled child, .10 and .12; Worry over specific fact, .09 and -.01; Leader, .09 and .05; Grouped: sensitive or worrisome, etc., .09 and .17; Nail-biting, .08 and .16; Poor work in school, .08 and .05; Depressed, .07 and .18; Discord between parents, .07 and .15; Repressed, .05 and .08; Speech defect, .05 and -.01; Truancy from school, .04 and .01; Sensitive over specific fact, .04 and .16; Gang, .03 (boys); Listless, .03 and .01; Refusal to attend school, .02 and .03; Sex denied entirely, .02 and .16; Popular, .01 and -.09; Vicious home conditions, .01 and -.02; Bashful, .00 and -.03; Headaches, -.01 and .04; Attractive manner, -.01 and -.08; Absent-minded, -.01 and -.09; Immoral home conditions, -.02 and -.02; Irregular attendance at school, -.02 and -.07; Former convulsions, -.02 and .11; Question of hypophrenia, -.03 and .06; Sex delinquency (coitus), -.03 and -.01; Clean, -.04 and -.03; Underweight, -.05 and .04; Oversuggestible, -.06 and .10; Lack of initiative, -.06 and -.06; Slow, dull, -.07 and .03; Grouped: dull, slow, etc., -.08 and .04; Retardation in school, -.08 and -.09; Apprehensive, -.08 and .08; Feeble-minded sibling, -.09 and -.07; Follower, -.09 and .06; Stuttering, -.09 (boys); Lues, -.11 and .01; Brother in penal detention, -.11 and .14

Omitted—Grouped: fighting, etc.

ties yielded substantial correlations in the .30's but low positive correlations ranging from .13 to .18 among boys: selfishness, lying, crying spells, restlessness, and distractibility.

Six behavior difficulties showed moderate correlations in the .20's with quarrelsomeness among both sexes: stubbornness, emotional instability, inferiority feelings, changeable moods or attitudes, inefficiency in work, play, etc., exclusion from school, and the three notations for which only the boys' correlations were calculated—threatening violence, swearing in general, and complaining of bad treatment by other children. Contrariness showed the low or moderate correlations of  $.21 \pm .05$  and  $.17$  for boys and girls respectively. Fifteen behavior traits among girls showed moderate correlations in the .20's but low positive correlations below .20 among boys: sulkiness, stealing, leading others into bad conduct, fantastical lying, slovenliness, irresponsibility, inattentiveness in school, daydreaming, "nervousness," restlessness in sleep, irregular sleep habits, finicky food habits, depressed spells or unhappiness (undifferentiated), enuresis, and staff notation of unfavorable conduct prognosis.

Among the sex notations, the physical or psychophysical disabilities, and the home or familial notations, the only statistically significant coefficient was for enuresis among girls,  $.22 \pm .04$ .

Violence (actual or attempted) was noted among 281, or 13.3 per cent, of our boys and among 87, or 7.4 per cent, of our girls. Among girls violence was a very grave indicator of behavior maladjustment in both the personality and the conduct categories. Its bi-serial correlation of  $.79 \pm .02$  was the largest but one of all the correlations with conduct-total (Table 7, p. 98), while its correlation of  $.64 \pm .03$  with personality-total was the largest of all correlations found among girls with personality-total (Table 6, p. 89). Among boys the correlation with conduct-total was high,  $.54 \pm .02$ , and with the personality-total somewhat substantial,  $.31 \pm .02$  (Table 71). Its tetrachoric correlations with the police-arrest criterion of "juvenile delinquency" was only moderate, the respective coefficients for boys and girls being  $.29 \pm .03$  and  $.18 \pm .05$ .

Among girls the three notations, swearing or bad language (undifferentiated), temper tantrums, and fighting, yielded very high correlations ranging from .61 to .64 with violence, the corresponding coefficients among boys being almost as large,  $.44 \pm .03$ ,

Lues.....	-.00	.20 ± .07 (70-71)

## Other Correlations (Positive to Negative)

Former convulsions, .17 and -.00; Smoking, .16 (boys); Apprehensive, .14 and .13; Gang, .14 (boys); Sex delinquency (coitus), .13 and .14; Question of hypophrenia, .13 and .11; Seclusive, .11 and .15; Lazy, .11 and .12; Bad companions, .11 and .09; Preference for younger children, .10 and .13; Lack of initiative, .09 and -.18; Inattentive in school, .09 and .18; Retardation in school, .08 and -.02; Discord between parents, .07 and .14; Absent-minded, .07 and .01; Irresponsible, .06 and .19; Psychoneurotic, .06 and .19; Repressed, .05 and -.04; Leader, .04 and .12; Irregular attendance at school, .04 and .06; Speech defect, .04 and .17; Popular, .03 and .11; Stuttering, .03 (boys); Sensitive over specific fact, .02 and .14; Grouped: sensitive or worrisome, etc., .02 and .14; Victim of sex abuse, .02 (girls); Poor work in school, .01 and .01; Clean, .01 and .06; Vicious home conditions, -.02 and .09; Sensitive (general),

TABLE 71—Continued

-.03 and .05; Underweight, -.03 and .03; Follower, -.04 and -.11; Immoral home conditions, -.05 and -.16; Brother in penal detention, -.06 and -.02; Sex denied entirely, -.08 and .09; Attractive manner, -.08 and .09; Grouped: dull, slow, etc., -.08 and .08; Bashful, -.11 and .01; Slow, dull, -.11 and .09; Vocational guidance, -.12 and -.13; Feeble-minded sibling, -.12 and -.12  
Omitted—Grouped: fighting, etc.

.54 ± .03, and .43 ± .03 respectively. Threatening violence among boys yielded a similarly high correlation of .54 ± .04, the corresponding coefficient for the girls not being calculated because of the paucity of cases. With quarrelsomeness and the larger grouping disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), the girls' correlations in the .50's also were high, with the boys' coefficients in the .40's almost as large.

Destructiveness yielded large correlations of .44 among both sexes. Among girls five behavior problems yielded large correlations in the .40's, with substantial corresponding correlations in the .30's among boys: incorrigibility, defiant attitude, disturbing influence in school, exclusion from school, and the larger grouping, "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated). Five undesirable conduct and personality traits among girls yielded similarly large correlations in the .40's, with moderate coefficients in the .20's among boys: disobedience, boastful or "show-off" manner, lying, unpopularity, and queer behavior. Five additional behavior problems among girls yielded large correlations in the .40's, but low positive coefficients below .20 among boys: bossy manner, leading others into bad conduct, "spoiled child," restlessness, and distractibility.

Three behavior problems—irritable temperament, rudeness, and emotional instability—together with teasing other children (calculated for boys only) and overinterest in the opposite sex (calculated for girls only) yielded uniformly substantial correlations in the .30's with violence. Among boys temper display and staff notation of unfavorable conduct prognosis yielded substantial correlations in the .30's, with moderate coefficients in the .20's among girls. Among girls six behavior problems yielded substantial correlations in the .30's, with moderate coefficients in

the .20's among boys: object of teasing by other children, stubbornness, contrariness, egocentricity, changeable moods and attitudes, and stealing. Ten additional miscellaneous notations among girls yielded substantial correlations in the .30's, but low positive correlations below .20 among boys: staying out late at night, fantastical lying, restlessness in sleep, question of change of personality, finicky food habits, mental conflict, daydreaming, slovenliness, overinterest in sex matters, and headaches.

Four behavior problems—sullenness, truancy from home, excuse-forming attitude, and irregular sleep habits—together with complaining of bad treatment by other children (calculated for boys only), showed moderate correlations in the .20's with violence. Three additional conduct problems—hatred or jealousy of sibling, refusal to attend school, and sulkiness—among boys showed moderate correlations in the .20's, with low positive correlations below .20 among girls. A large list of nineteen miscellaneous notations among girls similarly showed moderate correlations in the .20's but low positive coefficients below .20 among boys: selfishness, truancy from school, "nervousness," depressed mood or spells, unhappiness, crying spells, inferiority feelings, worry over some specific fact, listlessness, lack of interest in school, inefficiency in work, play, etc., loitering or wandering, oversuggestibility, enuresis, nail-biting, masturbation, question or diagnosis of encephalitis, neurological defect (unspecified), and lues.

Among the six sex notations there were three coefficients of moderate or substantial size ranging from .28 to .34, all among girls: masturbation, overinterest in sex matters, and (calculated for girls only) overinterest in the opposite sex.

Among the seven physical or psychophysical disabilities there were three moderate correlations in the .20's, all among girls: question or diagnosis of encephalitis, neurological defect (unspecified), and enuresis.

Among the four home or familial notations all coefficients were low or negligible, ranging from -.16 to .14.

Threatening violence or to kill someone was noted among 102, or 4.8 per cent, of our White boys. It occurred so rarely among girls that correlation coefficients were not practicable because of the paucity of girls' cases, and all the coefficients reported in

Table 72 were among boys only. Its bi-serial correlation with the conduct-total was high,  $.52 \pm .03$ . With the personality-total its bi-serial  $r$  was substantial,  $.34 \pm .03$ . With police arrest its tetrachoric  $r$  was moderate,  $.26 \pm .04$ .

High correlations in the .50's were found for violence and temper tantrums and large correlations in the .40's for swearing or bad language (undifferentiated) and destructiveness.

Substantial correlations in the .30's were found for the six behavior traits incurribility, irritable temperament, egocentricity, sullenness, swearing in general, and excuse-forming attitude.

Moderate correlations in the .20's were found for a large list of twenty-eight miscellaneous notations: fighting, quarrelsomeness, temper display, teasing other children, boastful or "show-off" manner, bossy manner, disobedience, defiant attitude, contrariness, disturbing influence in school, exclusion from school, complaining of bad treatment by other children, unpopularity, hatred or jealousy of sibling, rudeness, leading others into bad conduct, stealing, staying out late at night, irregular sleep habits, lying, lack of interest in school, "nervousness" or restlessness (undifferentiated), changeable moods or attitudes, queer behavior, daydreaming, question or diagnosis of encephalitis, headaches, and staff notation of unfavorable conduct prognosis.

The only negative correlation of probable statistical significance was with underweight condition,  $-.20 \pm .05$ .

Among the sex notations, the physical or psychophysical disabilities, and the home or familial notations the only correlations of probable statistical significance were with question or diagnosis of encephalitis,  $.22 \pm .07$ , and the negative correlation with underweight condition,  $-.20 \pm .05$ . All the other twelve coefficients in these fields were low or negligible, ranging from  $-.07$  to  $.13$ .

When the cases falling under the four rubrics, fighting, quarrelsomeness, violence, and threatening violence were combined into a broad grouping,<sup>1</sup> there were 644 such cases, or 30.5 per

---

<sup>1</sup>The reasons for this broader grouping were given in I, 44; see 86, Table 13, Item E.

Omitted—Grouped: fighting, etc.

cent, of the 2,113 White boys and 273, or 23.1 per cent, of the 1,181 White girls. These afforded some of the most numerous of the behavior difficulties or reasons for referring children for examination to the clinic in which this study was made. The fact that the resulting correlations as shown in Table 73 are generally similar to those of the four component notations but somewhat larger indicates the general similarity of these conduct notations.

Large or high coefficients in the .40's to .60's among both sexes were found for temper tantrums, swearing or bad language (undifferentiated), incurability, and destructiveness. Additional behavior notations yielding substantial to high correlations from the .30's to the 50's among both sexes were temper display, unpopularity, disturbing influence in school, disobedience, defiant attitude, rudeness, exclusion from school, "nervousness" or restlessness

## Other Correlations (Positive to Negative)

Refusal to attend school, .19 and .06; Truancy from school, .19 and .18; Lazy, .18 and .09; Overinterest in opposite sex, .18 (girls); Sex delinquency (coitus), .17 and .09; Overinterest in sex matters, .17 and .18; Gang, .17 (boys); Inefficient in work, play, etc., .17 and .13; Bad companions, .16 and .12; Depressed, .16 and .19; Psychoneurotic, .14 and .08; Leader, .11 and .10; Neurological defect, .11 and .11; Preference for younger children, .11 and .16; Seclusive, .10 and .03; Former convulsions, .09 and .09; Discord between parents, .08 and .16; Sensitive (general), .05 and .14; Poor work in school, .05 and -.01; Popular, .04 and .03; Listless, .04 and .05; Worry over specific fact, .04 and .07; Apprehensive, .04 and .10; Headaches, .03 and .11; Oversuggestible, .03 and .12; Question of hypophrenia, .03 and .02; Repressed, .02 and .11; Victim of sex abuse, .01 (girls); Retardation in school, -.02 and -.07; Brother in penal detention, -.02 and .12; Absent-minded, -.04 and .01; Attractive manner, -.04 and -.02; Clean, -.04 and .05; Speech defect, -.05 and .09; Stuttering, -.05 (boys); Follower, -.06 and .04; Lues, -.06 and .04; Underweight, -.06 and .07; Grouped: dull, slow, etc., -.07 and .05; Vicious home conditions, -.07 and .09; Irregular attendance at school, -.07 and -.03; Lack of initiative, -.07 and -.07; Sex denied entirely, -.07 and .09; Slow, dull, -.08 and .03; Feeble-minded sibling, -.08 and -.07; Vocational guidance, -.08 and -.16; Immoral home conditions, -.10 and .03; Bashful, -.10 and -.07

Omitted—Fighting; Quarrelsome; Threatening violence; Violence

(undifferentiated), irritable temperament, bossy manner, egocentricity, and (computed for boys only) teasing other children.

The following additional nineteen notations yielded moderate to large correlations from the .20's to the .40's among both sexes: contrariness, stubbornness, boastful or "show-off" manner, stealing, excuse-forming attitude, sullenness, lying, hatred or jealousy of sibling, selfishness, lack of interest or inattentiveness in school studies or employment (undifferentiated), queer behavior, emotional instability, changeable moods or attitudes, crying spells, complaining of bad treatment by other children (calculated for boys only), irregular sleep habits, smoking (calculated for boys only), question or diagnosis of encephalitis, and staff notation of unfavorable conduct prognosis. Among girls the following eight behavior difficulties yielded substantial or large correlations ranging from .30 to .46 but low positive coefficients below .20 among boys: leading others into bad conduct, object of teasing by other children, restlessness, restlessness in sleep, distractibility, irresponsibility, finicky food habits, and nail-biting.

Truancy from home among boys showed the moderate correlation of  $.27 \pm .03$  but a low coefficient of .16 among girls. The following fifteen personality and conduct problems among girls yielded moderate correlations in the .20's but low positive correlations below .20 among boys: staying out late at night, depressed spells or unhappiness (undifferentiated), fantastical lying, sulkiness, slovenliness, loitering or wandering, "spoiled child," mental conflict, inferiority feelings, daydreaming, question of change of personality, sensitiveness or worrisomeness (undifferentiated), sensitiveness over some specific fact, masturbation, and enuresis.

Among the six sex notations the larger grouping, fighting or quarrelsomeness (undifferentiated), showed only one statistically significant correlation,  $.27 \pm .04$ , with masturbation among girls.

Among the seven physical or psychophysical notations, moderate correlations in the .20's were found for question or diagnosis of encephalitis among both sexes and for enuresis among girls.

Among the home or familial notations all correlations were low or negligible.

## CHAPTER XXXIX

### DESTRUCTIVENESS

Destructiveness (breaking toys, windows, etc., or tearing books, clothing, etc.) was noted among 227, or 10.7 per cent, of our 2,113 White boys and among 55, or 4.7 per cent, of our 1,181 White girls. It appeared more frequently among the younger children, especially among the girls' cases.<sup>1</sup> Its bi-serial correlations in the .50's with conduct-total indicated its seriousness as a symptom of conduct deviation (Table 74). With the personality-total its correlations of  $.30 \pm .02$  among boys and  $.40 \pm .04$  among girls were substantial but not large. With the police-arrest criterion of "juvenile delinquency" its tetrachoric correlation among boys,  $.30 \pm .03$ , was similarly substantial but not large, while among girls the correlation was low,  $.15 \pm .06$ .

Its highest correlations were in the .40's among both sexes temper tantrums, violence, swearing or bad language (undifferentiated), and (calculated for boys only) threatening violence. In-corrigibility and stealing among boys yielded large correlations in the .40's with moderate correlations in the .30's among girls. Among girls five notations similarly yielded large correlations in the .40's, with substantial coefficients ranging from .29 to .39 among boys: contrariness, fighting, disobedience, leading others into bad conduct, and exclusion from school.

Three behavior problems yielded substantial correlations in the .30's among both sexes: disturbing influence in school, defiant attitude, and lying. Teasing other children (calculated for boys only) and overinterest in the opposite sex (calculated for girls only) also yielded substantial correlations in the .30's. Among boys four undesirable behavior traits yielded substantial correlations in the .30's with moderate correlations in the .20's among girls: rudeness, hatred or jealousy of sibling, fantastical lying, and excuse-forming attitude. Truancy

## Other Correlations (Positive to Negative)

Enuresis, .19 and .09; Loitering, .18 and .16; Unhappy, .18 and .11; Finicky food habits, .17 and .12; Refusal to attend school, .17 and .13; Overinterest in sex matters, .17 and .05; Sulky, .16 and .18; Irritable, .16 and .10; Object of teasing, .16 and .06; Inferiority feelings, .13 and .17; Lack of interest in school, .12 and .12; Crying spells, .12 and .13; Oversuggestible, .11 and .07; Grouped: depressed, etc., .10 and .19; Absent-minded, .09 and .17; Daydreaming, .09 and .11; Popular, .09 and -.02; Apprehensive, .08 and .09; Inefficient in work, play, etc., .08 and .19; Smoking, .08 (boys); Headaches, .07 and .15; Neurological defect, .06 and .12; Leader, .05 and -.01; Attractive manner, .05 and -.06; Clean, .04 and -.04; Irregular attendance at school, .03 and .03; Seclusive, .02 and .03; Psychoneurotic, .02 and .08; Follower, .02 and .06; Lues, .02 and .11; Sensitive over specific fact, .01 and .11; Poor work in school,

TABLE 74—Continued

.01 and .00; Underweight, .01 and .01; Brother in penal detention, .01 and .01; Listless, .00 and .09; Question of hypophrenia, .00 and .11; Immoral home conditions, -.00 and -.04; Retardation in school, -.01 and -.05; Grouped: sensitive or worrisome, etc., -.03 and .16; Depressed, -.02 and .17; Speech defect, -.03 and .18; Former convulsions, -.03 and .02; Sensitive (general), -.03 and -.08; Bashful, -.04 and -.04; Sex denied entirely, -.05 and -.02; Sex delinquency (coitus), -.06 and .02; Grouped: dull, slow, etc., -.07 and -.00; Slow, dull, -.07 and .00; Vocational guidance, -.09 and -.13; Stuttering, -.10 (boys)

from home among boys similarly yielded the substantial correlation of  $.31 \pm .03$  but a negative coefficient of  $-.16$  among girls. Among girls eight additional notations yielded substantial correlations in the .30's but low or negligible coefficients ranging between  $-.11$  to  $.22$  among boys: quarrelsomeness, emotional instability, distractibility, question of change of personality, queer behavior, mental conflict, worry over some specific fact, and question or diagnosis of encephalitis.

Six behavior problems showed moderate correlations in the .20's with destructiveness among both sexes: restlessness, ego-centricity, truancy from school, inattentiveness in school, staying out late at night, and masturbation, and the three notations for which only the boys' correlations were computed—swearing in general, running with a gang, and complaining of bad treatment by other children. Seven undesirable behavior traits among boys showed moderate correlations in the .20's but low coefficients below .20 among girls: bossy manner, boastful or "show-off" manner, sullenness, slovenliness, irresponsibility, "spoiled child", and unpopularity. Among girls thirteen miscellaneous notations showed moderate correlations in the .20's but low positive coefficients below .20 among boys: temper display, selfishness, stubbornness, bad companions, preference for younger children as playmates, "nervousness", nail-biting, restlessness in sleep, irregular sleep habits, changeable moods or attitudes, repressed manner, staff notation of unfavorable conduct prognosis, and discord between parents.

There were four negative correlations with destructiveness, all of moderate size in the  $-.20$ 's: laziness and vicious home conditions among girls, victim of sex abuse by older child or person (calculated for girls only), and feeble-minded sibling among boys.

Among girls the correlation of destructiveness with lack of

initiative could not be calculated because there were no instances in which the same girls were noted as manifesting both problems.

Among the six sex notations there were several correlations of statistically significant size: overinterest in the opposite sex (calculated for girls only),  $.32 \pm .06$ ; masturbation,  $.29 \pm .03$  among boys and  $.29 \pm .06$  among girls; and victim of sex abuse by older child or person,  $-.29 \pm .07$  (computed for girls only). The other correlations in this field were low or negligible.

Among the seven physical or psychophysical notations the only noteworthy correlation was the substantial coefficient of  $.33 \pm .10$  for question or diagnosis of encephalitis among girls.

Among the four home or familial notations there were two correlations of moderate size with destructiveness, both among girls:  $.20 \pm .06$  with discord between parents and the curious negative correlation of  $-.26 \pm .08$  with vicious home conditions.

CHAPTER XL

TEASING OR "PICKING ON" OTHER CHILDREN

Teasing or "picking on" other children in our data ranged all the way from bullying or cruelty down to merely annoying or "pestering" other children. It was noted among 210 of 2,113 White boys, or 9.9 per cent. It was noted so seldom among the girls' cases that reliable correlation coefficients could not be computed for them.

Its bi-serial correlations with the personality-total and conduct-total,  $.35 \pm .02$  and  $.41 \pm .02$  respectively, were substantial, but its tetrachoric correlation with police arrest was low,  $.14 \pm .03$  (Table 75).

TABLE 75

## Other Correlations (Positive to Negative)

Fantastical lying, .19; Overinterest in sex matters, .19; Question of change of personality, .19; Hatred or jealousy of sibling, .18; Absent-minded, .18; Egocentric, .18; Oversuggestible, .18; Complaining of bad treatment by other children, .18; Former convulsions, .18; Defiant, .17; Enurests, .17; Inefficient in work, play, etc., .17; Stealing, .17; Stubborn, .17; Daydreaming, .17; Poor work in school, .17; Lack of interest in school, .16; Nail-biting, .16; Changeable moods, .16; Bad companions, .15; Irresponsible, .15; Lazy, .15; Sulky, .15; Temper display, .15; Irritable, .15; Vicious home conditions, .15; Staying out late at night, .14; Bashful, .14; Loitering, .13; Sullen, .13; Refusal to attend school, .12; Truancy from home, .12; Depressed, .12; Listless, .12; Sensitive over specific fact, .12; Inferiority feelings, .12; Popular, .12; Attractive manner, .12; Neurological defect, .12; Contrary, .11; Queer, .11; Headaches, .11; Discord between parents, .11; Grouped: sensitive or worrisome, etc., .11; Finicky food habits, .10; Grouped: depressed, etc., .10; Object of teasing, .09; Repressed, .09; Clean, .09; Preference for younger children, .07; Follower, .07; Leader, .07; Seclusive, .06; Sex denied entirely, .06; Crying spells, .05; Mental conflict, .05; Underweight, .05; Vocational guidance, .05; Unhappy, .04; Stuttering, .03; Grouped: dull, slow, etc., .03; Question of hypophrenia, .02; Truancy from school, .01; Sex delinquency (coitus), .01; Irregular attendance at school, -.00; Speech defect, -.01; Slow, dull, -.01; Sensitive (general), -.02; Psychoneurotic, -.02; Brother in penal detention, -.04; Question of encephalitis, -.04; Feeble-minded sibling, -.05; Lack of initiative, -.05; Immoral home conditions, -.07; Gang, -.08; Retardation in school, -.09; Emotional instability, -.13; Lues, -.14

Its highest correlation was with disturbing influence in school,  $.45 + .03$ . Six correlations of substantial size in the .30's were found for violence, destructiveness, unpopularity, boastful or "show-off" manner, quarrelsomeness, and rudeness. A large list of twenty-five notations showed moderate correlations in the .20's: fighting, threatening violence, bossy manner, swearing in general, selfishness, incorrigibility, disobedience, temper tantrums, "spoiled child", restlessness, restlessness in sleep, "nervousness", irregular sleep habits, distractibility, apprehensiveness, leading others into bad conduct, smoking, excuse-forming attitude, exclusion from school, lying, worry over some specific fact, inattentiveness in school, slovenliness, masturbation, and staff notation of unfavorable conduct prognosis.

Among the four sex notations for which boys' correlations were calculated there were only two coefficients worthy of note, for masturbation,  $.21 + .03$ , and for overinterest in sex matters,  $.19$ .

Among the seven physical or psychophysical notations and the four home or familial notations, all coefficients were low or negligible, ranging from  $-.14$  to  $.15$ .

## CHAPTER XLI

### TEMPER TANTRUMS AND TEMPER DISPLAY

Since the rubric temper tantrums automatically includes temper display, it was not legitimate to calculate their intercorrelations. "Tantrums" characteristically applies to such bizarre behavior as throwing one's self on the floor, striking or biting one's self, or pounding one's head against the wall or floor. A comparison of their correlations with "outside" traits, as shown in the two tables in this chapter, indicates a considerable extent of similarity, but not enough to render unnecessary the separate statistical treatment of the two rubrics.

Both notations appeared with almost equal frequency among our cases. Of the two, temper tantrums appeared to be of greater "seriousness" or "ominousness."

Temper tantrums was noted among 221, or 10.5 per cent, of our 2,113 White boys and among 127, or 10.8 per cent, of our 1,181 White girls. Among girls its bi-serial correlations with the personality-total and conduct-total were both high,  $.54 \pm .03$  and  $.57 \pm .03$  respectively, while among boys these coefficients were substantial, the respective coefficients being  $.29 \pm .02$  and  $.38 \pm .02$  (Table 76). Its tetrachoric correlations with police arrest, however, were quite negligible.

Its highest correlations were with violence, the respective coefficients for boys and girls being  $.54 \pm .03$  and  $.61 \pm .04$ , and with threatening violence, with a coefficient of  $.53 \pm .04$  among boys, the girls' correlation being omitted because of paucity of cases. Among girls defiant attitude and "nervousness" or restlessness (undifferentiated) also yielded high correlations in the .50's, with substantial coefficients in the .30's among boys.

Destructiveness and swearing or bad language (undifferentiated) yielded large correlations in the .40's for both sexes. Among girls four notations yielded large correlations in the .40's, with substantial coefficients in the .30's among boys: irritable

TABLE 76—Continued

Worry over specific fact,  $-.07$  and  $.11$ ; Vicious home conditions,  $-.08$  and  $.13$ ; Sex denied entirely,  $-.08$  and  $.13$ ; Poor work in school,  $-.09$  and  $.05$ ; Slow, dull,  $-.14$  and  $.05$

Omitted—Grouped: temper, etc.; Temper display

temperament, fighting, incorrigibility, and rudeness. Among girls three additional notations yielded large correlations in the .40's, with moderate correlations in the .20's among boys: stubbornness, egocentricity, and boastful or "show-off" manner. Four additional notations among girls similarly yielded large correlations in the .40's but low positive coefficients below .20 among boys: disturbing influence in school, leading others into bad conduct, question of change of personality, and question or diagnosis of encephalitis.

Temper tantrums yielded substantial correlations in the .30's with quarrelsomeness among both sexes and with overinterest in the opposite sex, for which only the girls' correlation was calculated. Seven notations yielded substantial correlations in the .30's among girls with moderate coefficients in the .20's among boys: changeable moods or attitudes, emotional instability, "spoiled child," disobedience, finicky food habits, unpopularity, and exclusion from school. Among girls an additional eleven personality and conduct problems yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: restlessness, "nervousness," distractibility, crying spells, mental conflict, selfishness, excuse-forming attitude, sulkiness, sullenness, queer behavior, and depressed mood or spells.

Five behavior problems showed moderate correlations in the .20's with temper tantrums among both sexes: bossy manner, contrariness, lying, irregular sleep habits, and enuresis and also two conduct problems for which only the boys' coefficients were calculated, teasing other children and complaining of bad treatment by other children. Headaches among boys showed the moderate correlation of  $.23 \pm .05$  but a low positive coefficient of  $.16$  among girls. Among girls thirteen additional miscellaneous notations showed moderate correlations in the .20's but low positive coefficients below .20 among boys: restlessness in sleep, psychoneurotic trends, fantastical lying, irresponsibility, inattentiveness in school, lack of interest in school, slovenliness, truancy from school, stealing,

staying out late at night, masturbation, staff notation of unfavorable conduct prognosis, and neurological defect (unspecified).

Three negative correlations of moderate size in the  $-.20$ 's were found among the boys: feeble-minded sibling, brother in penal detention, and immoral home conditions.

Among the six sex notations temper tantrums showed moderate correlations of  $.28 \pm .05$  with masturbation among girls and  $.30 \pm .05$  with overinterest in the opposite sex (calculated for girls only).

Among the seven physical or psychophysical disabilities, question or diagnosis of encephalitis among girls yielded the large correlation of  $.40 \pm .07$  and neurological defect (unspecified) among girls the moderate correlation of  $.21 \pm .05$ . Enuresis showed moderate correlations of  $.20 \pm .03$  and  $.27 \pm .04$  among boys and girls respectively.

Among the four home or familial notations there were negative coefficients of moderate size in the  $-.20$ 's among boys for immoral home conditions and brother in penal detention.

Temper display (not "tantrums") was noted among 250, or 11.8 per cent, of our boys and among 93, or 7.9 per cent, of our girls. Among boys its bi-serial correlation with the personality-total, was of moderate size,  $.25 \pm .02$ , but all other correlations among both sexes with the personality-total, conduct-total, and police arrest were low, ranging from  $.06$  to  $.19$  (Table 77). One may conclude that temper display is of minor importance as an indicator of behavior difficulties.

Its highest correlations (in the  $.40$ 's) were found among girls for disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), and irritable temperament, the boys' coefficients also being substantial,  $.28 \pm .03$  and  $.30 \pm .03$  respectively.

Fighting yielded substantial correlations in the  $.30$ 's among both sexes. Violence yielded the substantial correlation of  $.39 \pm .03$  among boys, and a moderate coefficient of  $.26 \pm .06$  among girls. Among girls four conduct problems yielded substantial correlations in the  $.30$ 's, with moderate coefficients in the  $.20$ 's among boys: quarrelsomeness, stubbornness, bossy manner, and swearing or bad language (undifferentiated). Among girls an

## Other Correlations (Positive to Negative)

Disobedient, .19 and .19; Absent-minded, .19 and -.09; Queer, .18 and -.14; "Nervous," .18 and .03; Egocentric, .18 and .07; Boastful, "show-off," .17 and .08; Disturbing influence in school, .17 and .12; Refusal to attend school, .16 and .05; Crying spells, .16 and .15; Unpopular, .16 and .10; Headaches, .15 and .02; Distractible, .15 and -.03; Question of change of personality, .15 and .09; Teasing other children, .15 (boys); Enuresis, .15 and .10; Restless, .14 and .13; Conduct prognosis bad, .13 and -.05; Nail-biting, .12 and .11; Stealing, .12 and .13; Grouped: depressed, etc., .12 and .14; Truancy from school, .11 and .09; Slovenly, .10 and .04; Smoking, .10 (boys); Sensitive over specific fact, .10 and .07; Worry over specific fact, .10 and .03; Discard between parents, .10 and .11; Leader, .10 and .14; Exclusion from school, .10 and .03; Complaining of bad treatment by other children, .09 (boys); Depressed, .09 and .17; Inattentive in school, .09 and .01; Oversuggestible, .08 and -.02; Seclusive, .08 and -.07; Clean, .08 and .06; Speech defect, .07 and .02; Neurological defect, .07 and .04; Question of hypophrenia, .07 and -.06; Spoiled child, .07 and .09; Irregular sleep habits, .07 and .05; Loitering, .07 and .15; Bad companions, .06 and .03; Masturbation, .06 and -.07; Apprehensive, .06 and .02; Daydreaming, .06 and .14; Poor work in school, .06 and -.04; Lues, .06 and -.08; Brother in penal detention, .06 and -.08; Grouped: sensitive or worrisome, etc., .06 and .10; Grouped: dull, slow, etc., .05 and .03; Under weight, .05 and -.09; Retardation in school, .04 and -.04; Immoral home conditions, .03 and -.08; Irregular attendance at school, .03 and .09; Grouped: lack of interest in school, etc., .03 and .01; Follower, .03 and .10; Psychoneurotic, .02 and -.00; Stuttering, .02 (boys); Attractive manner, .01 and .02; Gang, .01 (boys); Bashful, -.00 and .04; Sex delinquency (coitus), -.00 and -.09; Overinterest in opposite sex, -.01 (girls); Lack of interest in school, -.01 and .00; Listless, -.01 and -.07; Lack of initiative, -.02 and -.12; Overinterest in sex matters, -.03 and -.11; Popular, -.04 and -.06; Preference for younger children, -.04 and .19; Sensitive (general), -.04 and .05; Inefficient in work, play, etc., -.04 and .17; Sex denied entirely, -.05 and -.14; Slow, dull, -.06 and .07; Leading others into bad conduct, -.13 and .10

Omitted—Grouped: temper, etc.; Temper tantrums

additional four conduct problems similarly yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: incorrigibility, hatred or jealousy of sibling, laziness, and rudeness.

Five behavior difficulties showed consistently moderate correlations in the .20's with temper display: changeable moods or attitudes, contrariness, selfishness, sulkiness, and (calculated for boys only) threatening violence. Among boys five miscellaneous notations showed moderate correlations in the .20's but low positive coefficients below .20 among girls: emotional instability, unhappiness, inferiority feelings, object of teasing by other children, and former convulsions. Eleven behavior problems among girls showed moderate correlations in the .20's but low coefficients below .20 among boys: destructiveness, defiant attitude, restlessness in sleep, sullenness, excuse-forming attitude, lying, fantastical lying, truancy from home, staying out late at night, finicky food habits, and irresponsibility.

There were six negative correlations of moderate size, ranging from  $-.31$  down to  $-.21$ , all among girls: feeble-minded sibling, mental conflict, repressed manner, "request for vocational guidance," question or diagnosis of encephalitis, and (calculated for girls only) victim of sex abuse by older child or person.

Among the six sex notations there was only one correlation of statistically significant size,  $-.21 \pm .06$  with victim of sex abuse by older child or person (calculated for girls only).

Among the seven physical or psychophysical notations all correlations were low or negligible, except the doubtfully significant negative coefficient of  $-.21 \pm .09$  with question or diagnosis of encephalitis among girls.

Among the four home or familial notations all correlations were low or negligible.

A "larger grouping" was made of the three similar notations, temper tantrums (Table 76), temper display (Table 77), and irritable temperament (Table 47, p. 274).<sup>1</sup> The resulting populations were 736, or 34.8 per cent, of our 2,113 White boys and 312, or 26.4 per cent, of our 1,181 White girls. This broader grouping

---

<sup>1</sup>The reasons for this broader grouping were given in I, 44; see 86, Table 13, Item C.

thus comprises one of the most frequent of behavior problems reported among our cases. The resulting coefficients (Table 78) were usually larger than those computed upon the more restricted rubrics.

It will suffice to summarize the coefficients for this larger grouping, temper tantrums or display (including irritable temperament, undifferentiated), briefly.

Four notations consistently yielded large or high coefficients ranging from .43 to .57: violence, swearing or bad language (undifferentiated), and the two notations for which only the boys' coefficients were calculated, threatening violence and swearing in general.

Thirteen notations yielded substantial or large correlations in the .30's and .40's among both sexes: fighting, quarrelsomeness, destructiveness, stubbornness, defiant attitude, contrariness, bossy manner, selfishness, question of change of personality, changeable moods or attitudes, "nervousness," crying spells, and question or diagnosis of encephalitis.

Twenty behavior problems among both sexes yielded moderate to high correlations ranging from the .20's to the .40's: incurability, disobedience, disturbing influence in school, exclusion from school, lying, fantastical lying, egocentricity, rudeness, sullenness, sulkiness, "spoiled child," hatred or jealousy of sibling, excuse-forming attitude, restlessness, restlessness in sleep, irregular sleep habits, finicky food habits, staff notation of emotional instability, queer behavior, and unpopularity and the two notations for which only the boys' correlations were computed—teasing other children and smoking.

Among the six sex notations there was one correlation of significant size,  $.20 \pm .04$  with overinterest in the opposite sex among girls, the boys' coefficient not being calculated because of paucity of cases.

Among the seven physical or psychophysical disabilities, question or diagnosis of encephalitis yielded the substantial coefficients of  $.31 \pm .04$  and  $.33 \pm .06$  for boys and girls respectively. Enuresis among girls yielded the substantial correlation of  $.31 \pm .03$ . Neurological defect (unspecified) among girls showed the moderate correlation of  $.24 \pm .04$ .

Among the four home or familial notations the only

minded sibling,  $-.11$  and  $-.17$ ; Victim of sex abuse,  $-.15$  (girls); Immoral home conditions,  $-.16$  and  $-.16$ ; Sex denied entirely,  $-.16$  and  $.04$   
Omitted--Temper display; Temper tantrums; Irritable

significant coefficient was the negative correlation of  $-.22 \pm .05$  with brother in penal detention among girls.

## CHAPTER XLII

### SWEARING AND BAD LANGUAGE

In the original indexing of the behavior problems and "reasons for referral" among the children examined consecutively in the behavior clinic at the Illinois Institute for Juvenile Research during the years 1923-27,<sup>1</sup> separate categories were set up for swearing or cursing in general; obscene, indecent, or suggestive language; profane, bad, or vile language (not including obscene language); and swearing at mother, stepmother, teacher, matriarch, etc., or "calling them names";<sup>2</sup> but these items were noted so infrequently that in spite of their clinical importance it was possible to calculate coefficients for only two categories—swearing in general among boys and swearing or bad language (including the four categories undifferentiated) among both sexes. These notations were important as indicators of conduct deviation, the girls' correlations being especially high, and, to a lesser extent, of personality deviation. As indicators of "juvenile delinquency," as measured by the correlations with police arrest, their significance was only moderate or low.

Swearing in general was noted among 137 of our 2,113 White boys, or 6.5 per cent. Among our 1,181 White girls it was noted in only 37 instances, too few to justify correlational treatment. With the conduct-total its bi-serial  $r$  was high,  $.51 \pm .02$ . With the personality-total its correlation was substantial,  $.30 \pm .03$ . With police arrest its tetrachoric  $r$  was low,  $.17 \pm .04$  (Table 79).

Swearing in general yielded large correlations in the .40's with the three notations temper tantrums, smoking, and violence. With six conduct problems it yielded substantial correlations in the .30's: incurability, fighting, threatening violence,

Omitted—Grouped: swearing, etc.

rudeness, lying, and stealing. A large list of twenty-four conduct and personality problems showed moderate correlations in the .20's: defiant attitude, disobedience, stubbornness, contrariness, quarrelsomeness, teasing other children, temper display, irritable temperament, destructiveness, truancy from home, staying out late at night, truancy from school, refusal to attend school, disturbing influence in school, exclusion from school, leading others into bad conduct, sullenness, excuse-forming attitude, unpopularity, inferiority feelings, queer behavior, masturbation, overinterest in sex matters, and enuresis.

The only negative correlation with swearing in general was for lack of initiative,  $-.29 \pm .03$ .

Among the four sex notations for which the boys' correlations were computed moderate correlations in the .20's were found for masturbation and overinterest in sex matters.

Among the seven physical or psychophysical disabilities the

only statistically significant correlation was with enuresis, .20 ± .04.

With the four home or familial notations the correlations with swearing in general were low or negligible.

The broader grouping, swearing or bad language (undifferentiated), was made up of the four categories described above: swearing or cursing in general; obscene, indecent, or suggestive language; profane, bad, or vile language (not including obscene language); and swearing at mother, stepmother, teacher, matron, etc., or "calling them names." It was noted among 278, or 13.2 per cent, of our 2,113 White boys and among 90, or 7.6 per cent, of our 1,181 White girls.

Among girls its unusually high bi-serial correlation of .76 ± .02 was one of the three highest of the girls' correlations found with conduct-total (Table 7, p. 98), and among boys its very high coefficient of .61 ± .02 was the highest of all the boys' correlations found with conduct-total. Its correlation with personality-total among girls was large, .43 ± .03, and among boys also substantial, .33 ± .02. With police arrest its respective tetrachoric r's for boys and girls were moderate or low, .23 ± .03 and .18 ± .05 (Table 80).

## Other Correlations (Positive to Negative)

Inferiority feelings, .17 and -.04; Gang, .16 (boys); Irresponsible, .16 and .08; Discord between parents, .16 and .15; Nail-biting, .15 and .16; Sulky, .15 and .06; Spoiled child, .13 and .02; Oversuggestible, .12 and .07; Depressed, .12 and .07; Inefficient in work, play, etc., .12 and .10; Neurological defect, .11 and .12; "Nervous," .11 and .07; Worry over specific fact, .10 and .19; Former convulsions, .08 and -.00; Sensitive over specific fact, .07 and .15; Seclusive, .06 and .10; Leader, .06 and .09; Absent-minded, .06 and .04; Preference for younger children, .04 and .12; Attractive manner, .04 and .09; Immoral home conditions, .04 and .14; Grouped: sensitive or worrisome, etc., .03 and .09; Repressed, .03 and .10; Clean, .02 and -.03; Sensitive (general), .01 and -.04; Stuttering, .00 (boys); Poor work in school, .00 and .03; Popular, -.00 and .01; Underweight, -.00 and .01; Question of hypophrenia, -.01 and .03; Psychoneurotic, -.01 and .10; Brother in penal detention, -.02 and .08; Listless, -.02 and .05; Retardation in school, -.03 and .06; Follower, -.04 and -.03; Sex denied entirely, -.05 and .03; Vocational guidance, -.05 and -.19; Grouped: dull, slow, etc., -.06 and .01; Slow, dull, -.06 and .03; Bashful, -.07 and -.11; Lues, -.09 and .13; Feeble-minded sibling, -.16 and .01; Speech defect, -.16 and -.04

Omitted—Swearing in general

Its highest correlation was with violence, among girls, .64 ± .05, the corresponding coefficient for boys also being large, .44 ± .03. Fighting among girls yielded the high correlation of .54 ± .03, the boys' coefficient, .35 ± .03, also being substantial. Five conduct problems yielded large correlations ranging

from .40 to .52 among both sexes: temper tantrums, incurrigibility, rudeness, destructiveness, and (calculated for boys only) threatening violence. Among girls seven undesirable behavior traits yielded large correlations in the .40's with corresponding substantial coefficients in the .30's among boys: quarrelsomeness, disturbing influence in school, stealing, staying out late at night, lying, excuse-forming attitude, and unpopularity. Leading others into bad conduct also yielded the high correlation of .43  $\pm$  .07 among girls but a moderate coefficient of .24  $\pm$  .04 among boys.

Four behavior difficulties yielded substantial correlations in the .30's among both sexes: disobedience, defiant attitude, contrariness, and overinterest in sex matters. Two traits, smoking (calculated for boys only) and overinterest in the opposite sex (calculated for girls only), also yielded substantial correlations in the .30's. Sullenness among boys yielded a substantial correlation of .34  $\pm$  .04 but a low coefficient of .19 among girls. Among girls thirteen conduct and personality traits yielded substantial correlations in the .30's with moderate corresponding coefficients in the .20's for boys: temper display, boastful or "show-off" manner, bossy manner, restlessness, irregular sleep habits, truancy from home, truancy from school, exclusion from school, loitering or wandering, fantastical lying, queer behavior, unhappiness, and staff notation of unfavorable conduct prognosis. Six notations among girls similarly yielded substantial correlations in the .30's but low positive correlations below .20 among boys: changeable moods or attitudes, question of change of personality, lack of interest in school, question or diagnosis of encephalitis, headaches, and vicious (not "immoral") home conditions.

Seven undesirable behavior problems showed moderate correlations in the .20's with swearing or bad language (undifferentiated) among both sexes: irritable temperament, stubbornness, egocentricity, hatred or jealousy of sibling, bad companions, slovenliness, and masturbation. Similar moderate correlations were found for two traits for which only the boys' coefficients were calculated—teasing other children and complaining of bad treatment by other children—and (calculated for girls only) victim of sex abuse by older child or person. Among girls sixteen notations showed moderate correlations in the .20's but corresponding low coeffi-

cients below .20 among boys: restlessness in sleep, emotional instability, distractibility, refusal to attend school, irregular attendance at school, inattentiveness in school, selfishness, mental conflict, daydreaming, crying spells, depressed spells or unhappiness (undifferentiated), apprehensiveness, object of teasing by other children, finicky food habits, sex delinquency (coitus), and enuresis.

Only one negative correlation was found, the moderate coefficient of  $-.29 \pm .07$ , with lack of initiative among girls.

Swearing or bad language (undifferentiated) tended to be significantly correlated with sex misbehavior among both sexes. Overinterest in sex matters among both sexes and overinterest in the opposite sex, for which only the girls' coefficients were calculated, all yielded substantial correlations of .32. Masturbation among both sexes and victim of sex abuse by older child or person, for which only the girls' correlations were calculated, showed moderate coefficients ranging from .20 to .27. Sex delinquency (coitus) among girls showed the moderate coefficient of  $.20 \pm .05$ , the corresponding coefficient for the boys being .05. For sex misbehavior denied entirely the two coefficients were negligible.

Among the six physical or psychophysical defects there were two correlations of statistically significant size, both among girls: question or diagnosis of encephalitis,  $.39 \pm .08$ , and enuresis,  $.28 \pm .05$ .

Among the four home or familial notations vicious (not "immoral") home conditions among girls yielded the substantial coefficient of  $.35 \pm .07$ , all other coefficients in this field being low or negligible.

## CHAPTER XLIII

### SMOKING

Smoking was noted among 190, or 9.0 per cent, of our 2,113 White boys. Among girls it was noted so infrequently (at least during the years 1923-27, during which period our cases were examined) that a correlational analysis among girls was not feasible. Among boys it was a fairly substantial indicator of conduct deviation and delinquency, but only a moderate index of personality disorder. It was a considerable indicator of conduct deviation and "juvenile delinquency," its correlations with conduct-total and police arrest being  $.49 \pm .02$  and  $.35 \pm .03$  respectively. With personality-total its bi-serial  $r$  of  $.21 \pm .03$  was of only moderate size.

Seven conduct problems yielded large tetrachoric correlations in the .40's (Table 81): leading others into bad conduct,

Lack of interest in school, .19; Threatening violence, .19; Grouped: lack of interest in school, etc., .18; Selfish, .18; Masturbation, .17; Popular, .17; Leader, .17; Grouped: "nervous," etc., .16; Nail-biting, .16; Sulky, .16; Violence, .16; Changeable moods, .16; Grouped: depressed, etc., .15; Egocentric, .15; Exclusion from school, .15; Sex delinquency (coitus), .14; Restless, .14; Depressed, .13; Follower, .13; Quarrelsome, .12; Temper tantrums, .12; Over-suggestible, .12; Irregular attendance at school, .12; Enuresis, .11; Inattentive in school, .10; Temper display, .10; Sensitive (general), .10; Unhappy, .10; Inefficient in work, play, etc., .09; Hatred or jealousy of sibling, .09; Distractible, .09; Conduct prognosis bad, .09; Clean, .09; Attractive manner, .09; Destructive, .08; Irresponsible, .08; Listless, .08; "Nervous," .08; Spoiled child, .08; Question of encephalitis, .08; Finicky food habits, .07; Daydreaming, .07; Worry over specific fact, .07; Inferiority feelings, .07; Complaining of bad treatment by other children, .07; Discord between parents, .07; Crying spells, .06; Sensitive over specific fact, .06; Grouped: sensitive or worrisome, etc., .05; Queer, .05; Poor work in school, .05; Bossy, .04; Stuttering, .04; Brother in penal detention, .04; Lazy, .02; Emotional instability, .02; Former convulsions, .02; Overinterest in sex matters, .01; Apprehensive, .01; Seclusive, .01; Repressed, .01; Object of teasing, -.00; Feeble-minded sibling, -.01; Underweight, -.01; Sex denied entirely, -.01; Mental conflict, -.01; Lues, -.03; Preference for younger children, -.04; Slow, dull, -.05; Grouped: dull, slow, etc., -.06; Psychoneurotic, -.06; Speech defect, -.08; Retardation

TABLE 81—Continued

in school,  $-.09$ ; Neurological defect,  $-.09$ ; Irregular home conditions,  $-.09$ ; Vicious home conditions,  $-.10$ ; Sentimental,  $-.10$ ; Question of hypochondria,  $-.13$ ; Vocational guidance,  $-.14$ ; Lack of initiative,  $-.14$ ; Bashful,  $-.18$

running with a gang, stealing, truancy from home, truancy from home, truancy from school, swearing in general, and lying. Five conduct problems yielded substantial correlations in the .30's: bad companions, staying out late at night, boastful or "show-off" manner, disobedience, and stubbornness.

A large list of twenty undesirable conduct or personality traits showed moderate correlations in the .20's: incorrigibility, contrariness, defiant attitude, refusal to attend school, fighting, disturbing influence in school, temper tantrums or display (undifferentiated), teasing other children, rudeness, irritable temperament, egocentricity or selfishness (undifferentiated), sullenness, loitering or wandering, slovenliness, irregular sleep habits, restlessness in sleep, excuse-forming attitude, fantastical lying, question of change of personality, and unpopularity.

One statistically significant negative correlation was found with smoking, the moderate coefficient of  $-.20 \pm .05$  with headaches.

Among the four sex notations, the seven physical or psychophysical defects, and the four home or familial notations for which the boys coefficients were calculated, the correlations were low or negligible, ranging from  $-.10$  to  $.17$ .

CHAPTER XLIV

ASSOCIATING WITH BAD COMPANIONS; RUNNING WITH  
A GANG; AND LEADING OTHERS INTO BAD CONDUCT

Three notations—associating with bad companions, running with a gang, and leading others into bad conduct—were of considerable importance as indicators of conduct deviation and juvenile delinquency but of lesser importance as indicators of personality difficulties.

Bad companions was noted among 370, or 17.5 per cent, of our 2,113 White boys and among 132, or 11.2 per cent, of our 1,181 White girls. With the police-arrest criterion of "juvenile delinquency" its tetrachoric correlation among boys was high,  $.59 \pm .02$ , and also fairly meaningful among girls,  $.40 \pm .04$  (Table 82). With

## Other Correlations (Positive to Negative)

Fighting, .19 and .17; Swearing (general), .19 (boys); Sex denied entirely, .19 and -.14; Quarrelsome, .18 and .09; Irregular sleep habits, .18 and .17; Discord between parents, .18 and .17; Slovenly, .17 and .13; Hatred or jealousy of sibling, .17 and .17; Sulky, .16 and .17; Sullen, .16 and .09; Grouped: fighting, etc., .16 and .12; Teasing other children, .15 (boys); Emotional instability, .15 and .17; Leader, .15 and .13; Irregular attendance at school, .15 and .05; Refusal to attend school, .14 and .14; Exclusion from school, .14 and .02; Spoiled child, .13 and .13; Attractive manner, .13 and -.01; Nail-biting, .11 and .04; Violence, .11 and .09; Apprehensive, .11 and .13; Mental conflict, .11 and .06; Enuresis, .10 and .00; Lazy, .10 and .11; Restless, .10 and .17; Complaining of bad treatment by other children, .10 (boys); Daydreaming, .09 and .05; Headaches, .09 and .10; Former convulsions,

TABLE 82—Continued

.09 and .02; Vocational guidance, .09 and -.07; Finicky food habits, .08 and .11; Grouped: depressed, etc., .08 and .09; Threatening violence, .07 (boys); Crying spells, .07 and .12; Restless in sleep, .07 and .09; Repressed, .07 and -.03; Popular, .07 and .10; Grouped: "nervous," etc., .07 and .09; "Nervous," .06 and -.02; Temper display, .06 and .03; Grouped: temper, etc., .06 and .02; Sensitive over specific fact, .06 and .11; Clean, .06 and -.06; Inefficient in work, play, etc., .05 and .14; Stubborn, .05 and .18; Temper tantrums, .04 and .09; Unpopular, .04 and .10; Inferiority feelings, .04 and -.01; Poor work in school, .04 and -.10; Immoral home conditions, .04 and .15; Contrary, .03 and .01; Irritable, .03 and -.03; Distractible, .03 and .09; Question of change of personality, .02 and .19; Object of teasing, .02 and .14; Preference for younger children, .02 and .12; Underweight, .01 and -.01; Grouped: sensitive or worrisome, etc., .00 and .16; Seclusive, -.01 and .00; Changeable moods, -.01 and .07; Selfish, -.03 and .11; Depressed, -.04 and .07; Listless, -.04 and -.13; Psychoneurotic, -.05 and .03; Neurological defect, -.06 and .06; Bashful, -.07 and -.11; Question of hypophrenia, -.07 and -.16; Grouped: dull, slow, etc., -.07 and -.16; Slow, dull, -.08 and -.15; Absent-minded, -.08 and -.00; Sensitive (general), -.10 and .04; Lack of initiative, -.10 and -.15; Speech defect, -.11 and -.07; Question of encephalitis, -.13 and .07; Lues, -.15 and .16

the conduct-total criterion of conduct disorders, not necessarily amounting to "juvenile delinquency," its correlations were substantial, its respective bi-serial  $r$ 's for boys and girls being  $.40 \pm .02$  and  $.35 \pm .03$ . With the personality-total criterion of personality difficulties its relationships were low or moderate, the respective correlations for boys and girls being  $.14 \pm .02$  and  $.22 \pm .03$ . It is probable that the high correlation with bad companions may illustrate the enhancing effect of what on pages 34-35 has been designated as "prejudicial" factors in case-record information when it is obtained in so large a degree from parents of the children. Parents are wont to excuse or explain the troubles of their own child by saying that other people's children have led him into bad conduct.

The highest correlations among boys were with stealing, the tetrachoric  $r$  being  $.57 \pm .02$ , while the corresponding girls' correlation was of only moderate size,  $.25 \pm .04$ . Among girls the highest correlation was with staying out late at night,  $.59 \pm .04$ , the corresponding boys' coefficient also being large,  $.44 \pm .03$ . Two conduct difficulties—truancy from school and oversuggestibility—yielded large correlations in the .40's among both sexes. Running with a gang, for which only the boys' correlation was calculated, and overinterest in the opposite sex, for which only the girls' correlation was calculated, similarly yielded large corre-

lations in the .40's. Truancy from home yielded correlations of  $.47 \pm .02$  and  $.21 \pm .05$  among boys and girls respectively.

Lying among both sexes and smoking (calculated for boys only) yielded substantial correlations in the .30's. Incorrigibility and loitering or wandering among boys similarly yielded substantial correlations in the .30's with moderate correlations in the .20's among girls. Leading others into bad conduct among boys yielded the substantial correlation of  $.37 \pm .04$  but a negligible coefficient of  $.05$  among girls. Among girls overinterest in sex matters yielded a substantial correlation of  $.32 \pm .06$ , the corresponding coefficient among boys being somewhat lower,  $.24 \pm .05$ . Sex delinquency (coitus) and worry over some specific fact among girls similarly yielded substantial correlations in the .30's but low respective coefficients of  $.14$  and  $-.01$  among boys.

Four notations—masturbation, swearing or bad language (undifferentiated), excuse-forming attitude, and vicious home conditions—showed moderate correlations in the .20's with bad companions among both sexes. Victim of sex abuse by older child or person, which was calculated for girls only, also showed the moderate correlation of  $.22 \pm .06$ . Among boys seven miscellaneous notations showed moderate correlations in the .20's but low coefficients below  $.20$  among girls: brother in penal detention, "follower," lack of interest in school, rudeness, boastful or "show-off" manner, unhappiness, and staff notation of unfavorable conduct prognosis. Among girls ten notations similarly showed moderate correlations in the .20's but low coefficients below  $.20$  among boys: disobedience, defiant attitude, egocentricity, bossy manner, irresponsibility, inattentiveness in school, disturbing influence in school, destructiveness, fantastical lying, and queer behavior.

Bad companions showed three negative correlations of moderate size in the  $-.20$ 's: stuttering (calculated for boys only) and retardation in school and feeble-minded sibling among girls.

Among sex-misbehavior notations there was a tendency toward positive correlation. Overinterest in the opposite sex (calculated for girls only) yielded the large correlation of  $.41 \pm .04$ . Sex delinquency (coitus) and overinterest in sex matters among girls yielded substantial correlations in the .30's with corresponding positive correlations of  $.14$  and  $.24 \pm .05$  among boys. Masturbation among both sexes and victim of sex abuse by older child or

person (calculated for girls only) showed moderate correlations in the .20's. Sex misbehavior denied entirely showed low correlation: of .19 and -.14 among boys and girls respectively.

Among the seven physical or psychophysical notations the only statistically significant correlation was the negative one of  $-.27 \pm .05$  with stuttering (calculated for boys only), all other coefficients being low or negligible, ranging from  $-.15$  to  $.16$ .

Among the four home or familial notations there were three coefficients of moderate size in the .20's: vicious home conditions among both boys and girls and brother in penal detention among boys.

Running with a gang was noted among 219, or 10.4 per cent, of our 2,113 White boys. Among girls it occurred so infrequently that the calculation of correlation coefficients was not feasible. Among boys its correlations resembled those of bad companions, as one might suppose, but in general were slightly smaller. Its tetrachoric correlation with police arrest was large,  $.45 \pm .03$ , its bi-serial correlation with the conduct-total was substantial,  $.35 \pm .02$ , but with personality-total the relationship was negligible,  $.09 \pm .02$ .

Its largest correlation was with stealing,  $.54 \pm .02$  (Table 83). Large correlations in the .40's were found for three

TABLE 83—Continued

iority feelings, -.07; Inefficient in work, play, etc., -.07; Worry over specific fact, -.08; Object of teasing, -.08; Teasing other children, -.08; Listless, -.09; Depressed, -.09; Speech defect, -.10; Psychoneurotic, -.10; Grouped: dull, slow, etc., -.11; Unpopular, -.11; Lack of initiative, -.11; Preference for younger children, -.12; Slow, dull, -.12; Bashful, -.12; Underweight, -.13; Headaches, -.16

conduct problems: bad companions, truancy from school, and smoking. Substantial correlations in the .30's were found for truancy from home, staying out late at night, loitering or wandering, oversuggestibility, and incurability.

Running with a gang showed moderate correlations in the .20's with a large list of nineteen miscellaneous notations: leading others into bad conduct, "leader," "follower," disobedience, defiant attitude, contrariness, refusal to attend school, egocentricity, boastful or "show-off" manner, sullenness, rudeness, destructiveness, fighting, lying, fantastical lying, slovenliness, staff notation of unfavorable conduct prognosis, sex misbehavior denied entirely, and brother in penal detention.

There were three negative correlations of moderate size in the -.20's: selfishness, stuttering, and "request for vocational guidance."

Among the four sex notations for which the boys' correlations were calculated the only significant correlation with running with a gang was the moderate one of  $.24 \pm .05$  with sex misbehavior denied entirely.

Among the seven physical or psychophysical disabilities the only significant coefficient was the negative one of  $-.24 \pm .05$  with stuttering.

Among the four home or familial notations the only significant correlation was with brother in penal detention,  $.20 \pm .05$ .

Leading others into bad conduct was noted among 138 boys, or 6.5 per cent, and among 50 girls, or 4.2 per cent. With the conduct-total its correlations were definitely high, the respective bi-serial  $r$ 's for boys and girls being  $.51 \pm .02$  and  $.65 \pm .03$  (Table 84). With the personality-total among girls its correlation was large,  $.45 \pm .04$ , but among boys only moderate,  $.20 \pm .03$ .

## Other Correlations (Positive to Negative)

Discord between parents, .16 and .03; Grouped: lack of interest in school, etc., .16 and .10; Enuresis, .14 and .10; Irregular sleep habits, .14 and .10; Distractible, .14 and .18; Temper display, .13 and .10; Inferiority feelings, .13 and .17; Victim of sex abuse, .13 (girls); Oversuggestible, .12 and .05; Restless in sleep, .12 and .05; Complaining of bad treatment by other children, .12 (boys); Sex denied entirely, .12 and -.13; Lues, .10 and -.05; Inattentive in school, .10 and -.12; Attractive manner, .09 and -.09; Preference

TABLE 84—Continued

for younger children, .08 and .11; Poor work in school, .08 and .10; Irregular attendance at school, .08 and -.02; Object of teasing, .07 and .08; Retardation in school, .07 and .08; Former convulsions, .07 and .13; Irritable, .06 and .13; Feeble-minded sibling, .06 and -.02; Clean, .05 and .07; Nail-biting, .04 and .08; Daydreaming, .03 and .16; Question of hypochondria, .03 and .14; Underweight, .03 and .13; "Nervous," .02 and .10; Follower, .02 and .09; Seclusive, .01 and .03; Repressed, .00 and .12; Immoral home conditions, -.00 and .18; Bashful, -.01 and .04; Popular, -.03 and .17; Finicky food habits, -.03 and .19; Grouped: dull, slow, etc., -.04 and -.05; Slow, dull, -.04 and -.04; Neurological defect, -.06 and .10; Apprehensive, -.06 and .14; Question of encephalitis, -.09 and .16; Lack of initiative, -.09 and -.06; Vocational guidance, -.12 and -.01; Sensitive (general), -.14 and .01; Headaches, -.15 and .03

With police arrest its tetrachoric  $r$  among boys was definitely substantial,  $.40 \pm .04$ , but only moderate among girls,  $.27 \pm .06$ .

Among boys its largest correlations were with smoking (calculated for boys only),  $.48 \pm .04$ . Among boys stealing also yielded the large correlation of  $.46 \pm .03$ , the corresponding coefficient for girls being low, .16. Among girls exclusion from school and destructiveness yielded its largest correlations,  $.47 \pm .07$  and  $.47 \pm .08$  respectively, the corresponding coefficients for boys being substantial,  $.31 \pm .05$  and  $.31 \pm .04$ . Five undesirable behavior traits among girls similarly yielded large correlations in the .40's with moderate coefficients in the .20's among boys: overinterest in sex matters, swearing or bad language (undifferentiated), rudeness, sullenness, and unpopularity. An additional five behavior problems among girls yielded large coefficients in the .40's but low coefficients ranging from -.02 to .12 among boys: sex delinquency (coitus), violence, temper tantrums, contrariness, and queer behavior.

Leading others into bad conduct yielded consistently substantial correlations in the .30's for the five notations: incorrigibility, staying out late at night, lying, boastful or "show-off" manner, and (calculated for girls only) overinterest in the opposite sex. Three notations—truancy from school, disturbing influence in school, and truancy from home—among boys yielded substantial correlations in the .30's with moderate coefficients in the .20's among girls. Bad companions and "leader" among boys yielded substantial correlations in the .30's but low coefficients below .20 among girls. Among girls five conduct problems yielded substantial correlations in the .30's with moderate coefficients

in the .20's among boys: disobedience, defiant attitude, fighting, fantastical lying, and masturbation. Among girls an additional six behavior notations yielded substantial correlations in the .30's but low coefficients below .20 among boys: mental conflict, question of change of personality, emotional instability, listlessness, irresponsibility, and staff notation of unfavorable conduct prognosis.

Six notations consistently showed moderate correlations in the .20's: egocentricity, slovenliness, brother in penal detention, and the three traits for which only the boys' correlations were computed—running with a gang, threatening violence, and teasing other children. Four undesirable traits among boys showed moderate correlations in the .20's but low positive coefficients below .20 among girls: refusal to attend school, excuse-forming attitude, loitering or wandering, and inefficiency in work, play, etc. Among girls a large list of eighteen miscellaneous notations showed moderate correlations in the .20's but low coefficients below .20 among boys: bossy manner, selfishness, stubbornness, "spoiled child," sulkiness, hatred or jealousy of sibling, quarrelsomeness, restlessness, lack of interest in school, laziness, changeable moods or attitudes, crying spells, depressed mood or spells, unhappiness, sensitiveness over some specific fact, worry over some specific fact, psychoneurotic trends, and vicious home conditions.

Leading others into bad conduct showed negative moderate correlations in the -.20's with speech defect among girls and with stuttering (calculated for boys only).

With sex misbehavior leading others into bad conduct tended to be significantly associated. Sex delinquency (coitus) and over-interest in sex matters among girls yielded large correlations in the .40's, the respective boys' coefficients of .11 and .21  $\pm$  .06 being low or moderate. Overinterest in the opposite sex (calculated for girls only) yielded the substantial correlation of .37  $\pm$  .06. With masturbation the respective coefficients for girls and boys were .36  $\pm$  .06 and .25  $\pm$  .04. For sex misbehavior denied entirely and victim of sex abuse by older child or person (calculated for girls only) the coefficients were low or negligible.

Among the seven physical or psychophysical disabilities the only significant correlations found were the moderate negative

ones of  $-.27 \pm .08$  for speech defect (other than stuttering) among girls and  $-.20 \pm .06$  for stuttering (calculated for boys only).

Among the four home or familial notations moderate positive correlations in the .20's were found for brother in penal detention among both boys and girls and for vicious (not "immoral") home conditions among girls.

CHAPTER XLV

LOITERING; LAZINESS; INEFFICIENCY;  
IRRESPONSIBILITY

The four behavior notations, loitering or wandering, laziness, inefficiency in work, play, etc., and irresponsibility, are grouped together in the present chapter only as a matter of convenience. They are not greatly similar to each other as far as may be inferred either from their intercorrelations or from their "outside" correlations with other traits.

Loitering or wandering, loafing or bumming on the street or in pool halls, dance halls, and the like, was noted among 174, or 8.2 per cent, of our 2,113 White boys and 61, or 5.2 per cent, of our 1,181 White girls. Among boys its correlations with the conduct-total and police-arrest criteria of seriousness were of fairly large size in the .40's but of only moderate size, .23 ± .03, with the personality-total criterion (Table 85). Among girls

## Other Correlations (Positive to Negative)

Vicious home conditions, .19 and .14; Boastful, "show-off," .18 and .16; Destructive, .18 and .16; Swearing (general), .18 (boys); Restless, .18 and .14; Grouped: lack of interest in school, etc., .18 and .10; Absent-minded, .17 and -.10; Quarrelsome, .16 and .07; Masturbation, .16 and .00; Egocentric, .16 and -.02; Feclusive, .16 and -.03; Grouped: egocentric, etc., .14 and .06; Lazy, .13 and .15; Nail-biting, .13 and .06; Teasing other children, .13 (boys); Leader, .13 and .11; Headaches, .13 and .13; Grouped: temper, etc., .13 and .11; Bossy, .12 and -.03; Sulky, .12 and .09; Temper tantrums, .12 and .09; Overinterest in sex matters, .12 and .14; Hatred or jealousy of sibling, .12 and -.09; Discord between parents, .12 and .08; Rude, .11 and .02; Poor work in school, .11 and .08; Attractive manner, .11 and .01; Former convulsions, .11 and -.06; Grouped: "nervous," etc., .11 and .11; Complaining of bad treatment by other children, .10 (boys); Queation of hypophrenia, .10 and .15; Stubborn, .09 and .02; Excuse-forming, .09 and .13; Crying spells, .08 and -.01; Grouped: depressed, etc., .07 and -.07; Temper display, .07 and .15; Daydreaming, .07 and -.06; Irritable, .07 and .06; Sex denied entirely, .07 and -.18; Underweight, .07 and -.07; Contrary, .06 and .10; Bashful, .06 and -.18; Object of teasing, .06 and -.04; Follower, .06 and -.02; Neurological defect, .06 and -.06; Brother in penal detention, .06 and -.02; Listless, .05 and .02; Lack of initiative, .05 and -.11; Inattentive in school, .04 and .14; Restless in sleep, .04 and .18; Lues, .04 and .13; Enuresis, .03 and .12; "Nervous," .03 and -.04; Preference for younger children, .03 and - 00; Apprehensive, .02 and .06; Immoral home conditions, .02 and .08; Selfish, .01 and .01; Depressed, .01 and .01; Sensitive over specific fact, .01 and -.13; Grouped: dull, slow, etc., .01 and .00; Grouped: sensitive or worrisome, etc., -.10 and -.04; Slow, dull, -.00 and .01; Worry over specific fact, -.01 and .16; Threatening violence, -.01 (boys); Changeable moods, -.02 and .09; Finicky food habits, -.02 and .15; Victim of sex abuse, -.02 (girls); Stuttering, -.03 (boys); Sensitive (general), -.03 and -.05; Feeble-minded sibling, -.04 and -.07; Psychoneurotic, -.08 and -.02; Retardation in school, -.08 and .04; Mental conflict, -.17 and -.17

the correlations with conduct-total and police arrest were of only moderate size, in the .20's, and its correlation with personality-total negligible.

The highest correlation with loitering or wandering was with truancy from home,  $.53 \pm .03$ , the corresponding correlation among girls being moderate,  $.25 \pm .06$ . Staying out late at night and truancy from school among boys yielded the large correlations of  $.46 \pm .03$  and  $.49 \pm .03$ , the corresponding coefficients among girls being almost as large,  $.49 \pm .06$  and  $.39 \pm .06$  respectively.

Four notations consistently yielded substantial correlations in the .30's: stealing, lying, and (calculated for boys only) running with a gang, and (calculated for girls only) overinterest in the opposite sex. Fantastical lying and bad companions among boys yielded substantial correlations in the .30's with moderate correlations in the .20's among girls. Three notations—

irresponsibility, slovenliness, and refusal to attend school—among boys yielded substantial correlations in the .30's but low coefficients below .20 among girls. Among girls incurrigibility yielded the substantial correlation of  $.34 \pm .05$ , with a moderate correlation of  $.28 \pm .03$  among boys. Sex delinquency (coitus) among girls also yielded the substantial correlation of  $.33 \pm .05$  but a low coefficient of .16 among boys.

Smoking among boys showed the moderate correlation of .28  $\pm .04$  with loitering or wandering, the girls' coefficient not being calculated because of paucity of cases. Among boys the following thirteen behavior notations showed moderate correlations in the .20's but low coefficients below .20 among girls: inefficiency in work, play, etc., irregular attendance at school, lack of interest in school, disturbing influence in school, exclusion from school, leading others into bad conduct, distractibility, fighting, disobedience, "spoiled child," unpopularity, emotional instability, and staff notation of unfavorable conduct prognosis. Among girls six notations showed moderate correlations in the .20's but low positive coefficients below .20 among boys: irregular sleep habits, defiant attitude, violence, question of change of personality, queer behavior, and question or diagnosis of encephalitis.

With loitering or wandering there were six statistically significant negative correlations, ranging from  $-.21$  to  $-.34$ , all among girls, the corresponding boys' coefficients being negligible: unhappiness, inferiority feelings, sullenness, clean habits, speech defect (other than stuttering), and "request for vocational guidance."

For two notations, repressed manner and popularity, the tetrachoric coefficients among girls could not be calculated because there were no instances in which girls with either of these notations also were noted as given to loitering or wandering.

Among the six sex notations there were two correlations of substantial size in the .30's, both among girls: sex delinquency (coitus) and (calculated for girls only) overinterest in the opposite sex.

Among the seven physical or psychophysical disabilities speech defect (other than stuttering) yielded the substantial negative coefficient of  $-.31 \pm .07$  among girls. Question or diagnosis of encephalitis among girls showed the doubtfully significant coefficient of  $.25 \pm .10$ .

Among the four home or familial notations all correlations with loitering or wandering were low or negligible.

Laziness was noted among 182 boys, or in 8.6 per cent of our cases, and among 79 girls, or 6.7 per cent. With the personality-total and conduct-total its correlations among boys were moderate, the bi-serial  $r$ 's being  $.29 \pm .02$  and  $.22 \pm .03$  respectively (Table 86), and low among girls, the coefficients in both instances being  $.17 \pm .04$ . With police arrest the girls' tetrachoric  $r$  of  $.30 \pm .05$  was perhaps substantial, but the boys' coefficient of  $-.05 \pm .04$  was quite negligible. Laziness may, therefore, be considered to be of minor importance or seriousness from the standpoint of personality or conduct deviation.

Its largest correlation,  $.41 \pm .06$ , was among girls for inefficiency in work, play, etc., the corresponding coefficient for boys,  $.34 \pm .05$ , being also substantial. Among boys listlessness and poor work in school yielded substantial correlations in the .30's, with moderate coefficients in the .20's among girls. Irresponsibility and slovenliness among girls yielded substantial correlations in the .30's, with moderate coefficients in the .20's among boys. Temper display among girls similarly yielded the substantial correlation of  $.35 \pm .06$ , but a low coefficient of .11 among boys.

Six behavior problems showed moderate correlations in the .20's with laziness among both sexes: lack of initiative or ambition, inattentiveness in school, lack of interest in school, boastful or "show-off" manner, rudeness, and unpopularity. Nine undesirable behavior traits among boys showed moderate correlations in the .20's, but low or negligible coefficients below .20 among girls absent-mindedness, distractibility, selfishness, disobedience, swearing or bad language (undifferentiated), disturbing influence in school, inferiority feelings, unhappiness, and masturbation. Eleven notations among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: stubbornness, contrariness, defiant attitude, bossy manner, leading others into bad conduct, preference for younger children as playmates, seclusiveness, depressed mood or spells, irregular sleep habits, enuresis, and "request for vocational guidance."

Laziness showed three negative correlations of moderate

Other Correlations (Positive to Negative)

Daydreaming, .19 and .09; Attractive manner, .19 and .05; Lying, .18 and .13; Slow, dull, .18 and .14; Grouped: fighting, etc., .18 and .09; Quarrelsome, .17 and .14; Sullen, .17 and -.00; Hatred or jealousy of sibling, .17 and .17; Bashful, .16 and -.07; Sensitive over specific fact, .16 and -.01; Queer, .16 and .17; Mental conflict, .16 and -.00; Spoiled child, .16 and .11; Grouped: egocentric, etc., .16 and .09; Teasing other children, .15 (boys); Repressed, .15 and .10; Grouped: sensitive or worrisome, etc., .15 and .01; Overinterest in opposite sex, .15 (girls); Clean, .14 and .04; Loitering, .13 and .15; Sulky, .13 and .12; Swearing (general), .13 (boys); Sensitive (general) .13 and .10; Complaining of bad treatment by other children, .13 (boys); Object of teasing, .12 and .07; Grouped: "nervous," etc., .12 and .09; Violence, .12 and .12; Overinterest in sex matters, .11 and -.01; Irritable, .11 and .11; Follower, .11 and -.04; Bad companions, .10 and .11; Fighting, .10 and .09; Nail-biting, .10 and .01; Headaches, .09 and .11; Truancy from school, .09 and .06; Finicky food habits, .08 and .06; Fantastical lying, .08 and .09; Truancy from home, .08 and -.05; Excuse-forming, .08 and .14; Restless, .08 and .08; Exclusion from school, .07 and .13; Discord between parents, .07 and .06; Crying spells, .06 and .03; Egocentric, .06 and .05; Restless in sleep, .06 and .04; Stuttering, .06 (boys); Former convulsions, .06 and -.02; Refusal to attend school, .05 and -.04; Popular, .05 and -.02; Immoral home conditions, .05 and .12; Incurable, .04 and .08; Temper tantrums, .04 and .00; Apprehensive, .04 and -.02; Changeable moods, .03 and .01; Emotional instability, .03 and .09; Lues, .03 and .01; Smoking, .02 (boys); Staying out late at night, .02 and .05; Question of change of personality, .02 and .09; Leader, .02 and -.11; Stealing, .01 and .11; Neurological defect, .01 and -.06; Speech defect, .01 and -.14; Brother in penal detention, -.02 and -.04; Conduct prognosis bad, -.02 and .01; Victim of sex abuse, -.02 (girls); "Nervous," -.02 and -.01; Psychoneurotic, -.02 and -.02; Threatening violence, -.02 (boys); Gang, -.02 (boys) Oversuggestible, -.03 and .03; Irregular attendance at school, -.04 and .14; Underweight, -.05 and .02; Vicious home conditions, -.07 and .02; Worry over specific fact, -.08 and -.00; Question of hypophrenia, -.10 and .06; Feeble-minded sibling, -.18 and -.13

size in the -.20's: sex delinquency (coitus) among boys and destructiveness and retardation in school among girls.

Among the six sex notations there were two correlations of moderate size with laziness, both among boys, the interesting negative one of  $-.28 \pm .06$  with sex delinquency (coitus) and the positive one of  $.20 \pm .03$  with masturbation.

Among the seven physical or psychophysical defects the only statistically significant correlation was  $.26 \pm .05$  with enuresis among girls.

Among the four home or familial notations all coefficients were negligible, ranging from  $-.07$  to  $.12$ .

The notation inefficiency or carelessness in work, studies, play, etc., forgetting errands, etc., was found among 106 boys, or 5.0 per cent of our cases, and among 75 girls, or 6.4 per cent. Its bi-serial correlations with the personality-total were large,  $.42 \pm .03$  and  $.50 \pm .03$  for boys and girls respectively (Table 87). With the conduct-total its correlation among boys was moderate,  $.24 \pm .03$ , and among girls substantial,  $.35 \pm .04$ . With police arrest its tetrachoric correlations were negligible.

Its largest correlations among both sexes were with absent-mindedness, with coefficients in the .40's. Irresponsibility among boys also yielded the large correlation of  $.47 \pm .05$ , with a substantial coefficient among girls of  $.35 \pm .07$ . Laziness among girls yielded the large correlation of  $.41 \pm .06$ , with a substantial coefficient of  $.34 \pm .05$  among boys. Daydreaming and depressed mood or spells among girls similarly yielded large correlations in the .40's with moderate coefficients in the .20's among boys.

Distractibility and queer behavior yielded substantial correlations ranging from  $.29$  to  $.36$  among both sexes. Among girls three behavior problems, slovenliness, emotional instability, and changeable moods or attitudes, yielded substantial correlations in the .30's with moderate coefficients in the .20's among boys. Among girls four additional conduct problems yielded substantial correlations in the .30's but low coefficients below  $.20$  among boys: excuse-forming attitude, lying, defiant attitude, and boastful or "show-off" manner.

Seven behavior traits showed consistent moderate correlations with inefficiency in work, play, etc., in the .20's: listlessness, lack of interest in school, poor work in school, sensitiveness in general, crying spells, stubbornness, and quarrelsomeness, and also one calculated for girls only, overinterest in the opposite sex. Nine notations among boys showed moderate correlations in the .20's but low coefficients below  $.20$  among girls:

## Other Correlations (Positive to Negative)

Staying out late at night, .19 and .08; Contrary, .18 and .05; Lies, .18 and .11; Teasing other children, .17 (boys); Complaining of bad treatment by other children, .17 (boys); Grouped: fighting, etc., .17 and .13; Stuttering, .16 (boys); Preference for younger children, .15 and .18; Neurological defect, .15 and .16; Discord between parents, .15 and .06; Disobedient, .14 and .13; Selfish, .14 and .19; Restless in sleep, .14 and .14; Sensitive over specific fact, .14 and .17; Worry over specific fact, .14 and .16; Refusal to attend school, .13 and -.03; Irritable, .13 and .18; Object of teasing, .13 and .08; Truancy from school, .12 and .02; Grouped: swearing, etc., .12 and .10; Sullen, .11 and .16; Masturbation, .11 and .08; "Nervous," .10 and .18; Former convulsions, .10 and -.01; Bossy, .09 and .10; Incurable, .09 and .14; Nail-biting, .09 and -.02; Smoking, .09 (boys); Truancy from home, .09 and .13; Attractive manner, .09 and .06; Vocational guidance, .09 and -.17; Destructive, .08 and .19; Overinterest in sex matters, .08 and .14; Bashful, .08 and .02; Egocentric, .08 and .09; Oversuggestible, .08 and .12; Popular, .08 and -.00; Threatening violence, .07 (boys); Hatred or jealousy of sibling, .07 and .18; Fighting, .06 and .09; Temper tantrums, .06 and .18; Sex delinquency (coitus), .06 and .01; Bad companions, .05 and .14; Finicky food habits, .05 and -.06; Apprehensive, .05 and .12; Follower, .05 and .06; Enuresis, .04 and .19; Swearing (general), .04 (boys); Feeble-minded sibling, .04 and -.12; Repressed, .01 and .11; Victim of sex abuse, -.00 (girls); Underweight, -.00 and .04; Question of hypophrenia, -.00 and .04; Clean, -.02 and .06; Leader, -.02 and -.11; Psychoneurotic, -.02 and .10; Sex denied entirely, -.04 and .13; Temper display, -.04 and .17; Retardation in school, -.07 and -.02; Gang, -.07 (boys); Brother in penal detention, -.12 and -.19; Vicious home conditions, -.13 and .09

lack of initiative or ambition, inattentiveness in school, loitering or wandering, "spoiled child," restlessness, unhappiness, seclusiveness, leading others into bad conduct, and question or diagnosis of encephalitis. Among girls nineteen miscellaneous notations showed moderate correlations in the .20's but low or negligible coefficients below .20 among boys: slow or dull manner, fantastical lying, mental conflict, inferiority feelings, question of change of personality, egocentricity or selfishness (undifferentiated), rudeness, sulkiness, "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated), irregular sleep habits, disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), violence, temper tantrums or display (including irritable temperament, undifferentiated), disturbing influence in school, exclusion from school, stealing, staff notation of unfavorable conduct prognosis, immoral home conditions, and headaches.

There were two negative correlations of statistically significant size with inefficiency in work, play, etc., both among girls: speech defect (other than stuttering),  $-.33 \pm .07$ , and irregular attendance at school,  $-.20 \pm .07$ .

Among the six sex notations the only significant correlation was  $.20 \pm .06$  for overinterest in the opposite sex, for which only the girls' correlations were calculated.

Among the seven physical or psychophysical disabilities there were two statistically significant correlations, the positive one of  $.20 \pm .07$  with question or diagnosis of encephalitis among boys and the curious negative one of  $-.33 \pm .07$  with speech defect (other than stuttering) among girls.

Among the four home or familial notations the only correlation of statistically significant size was with immoral home conditions among girls,  $.23 \pm .07$ .

Irresponsibility was noted among 118 of our boys, or 5.6 per cent, and among 70 of our girls, or 5.9 per cent. With the personality-total and conduct-total its correlations were moderate, ranging from .24 to .32 (Table 88). With police arrest its correlations were negligible.

Its largest correlation among boys was  $.47 \pm .05$  with inefficiency in work, play, etc., the corresponding coefficient for

TABLE 88

## Other Correlations (Positive to Negative)

Irritable, .19 and .16; Lack of initiative, .19 and .08; Poor work in school, .19 and .09; Boastful, "show-off," .18 and .16; Bossy, .18 and .17; Refusal to attend school, .18 and -.01; Mental conflict, .18 and .03; Excuse-forming, .17 and .18; Restless, .17 and .16; Preference for younger children, .17 and .07; Contrary, .16 and .13; Changeable moods, .16 and .08; Seclusive, .16 and .01; Grouped: "nervous," etc., .16 and .19; Grouped: swearing, etc., .16 and .08; Teasing other children, .15 (boys); Rude, .15 and .15; Popular, .15 and .02; Grouped: dull, slow, etc., .15 and -.03; Truancy from school, .14 and .04; Exclusion from school, .14 and .16; Inattentive in school, .13 and .09; Overinterest in sex matters, .13 and .03; Irregular sleep habits, .13 and .17; Masturbation, .12 and .05; Leader, .12 and .19; Neurological defect, .12 and -.03; Object of teasing, .11 and .15; Complaining of bad treatment by other children, .11 (boys); Egocentric, .10 and .15; Threatening violence, .09 (boys); Smoking, .08 (boys); Oversuggestible, .08 and .18; Attractive manner, .08 and .12; Discord between parents, .08 and .11; Hatred or jealousy of sibling, .07 and .10; Slow, dull, .07 and -.03; Restless in sleep, .07 and .11; Irregular attendance at school, .07 and -.06; Brother in penal detention, .07 and -.05; Gang, .06 (boys); Violence, .06 and .19; "Nervous," .06 and .14; Follower, .06 and .08; Vocational guidance, .06 and -.08; Stubborn, .05 and .12; Apprehensive, .05 and .05; Inferiority feelings, .04 and .13; Repressed, .04 and -.17; Underweight, .04 and .04; Sulky, .03 and .06; Depressed, .02 and .18; Stuttering, .02 (boys); Bashful, .01 and -.03; Former convulsions, .01 and -.17; Sensitive (general), .00 and .06; Swearing (general), -.01 (boys); Sullen, -.01 and -.01; Finicky food habits, -.01 and .06; Enuresis, -.02 and .07; Victim of sex abuse, -.03 (girls); Lues, -.04 and -.06; Psychoneurotic, -.04 and .13; Grouped: sensitive or worrisome, etc., -.05 and .13; Speech defect, -.05 and .06; Clean, -.07 and .06; Question of hypophrenia, -.10 and .01; Sex denied entirely, -.11 and .02; Sex delinquency (coitus), -.14 and .11

girls being substantial,  $.35 \pm .07$ . Among girls its largest correlation was  $.46 \pm .04$  with lying, the corresponding coefficient for boys being only moderate,  $.21 \pm .04$ .

Three behavior problems—loitering or wandering, absent-mindedness, and staying out late at night—among boys yielded substantial correlations in the .30's but low coefficients below .20 among girls. Laziness among girls yielded the substantial correlation of  $.36 \pm .07$  and among boys the moderate coefficient of  $.28 \pm .05$ . Five behavior traits among girls yielded substantial correlations in the .30's but low coefficients below .20 among boys: disobedience or incorrigibility (undifferentiated), selfishness, fighting, leading others into bad conduct, and unhappiness.

Irresponsibility showed consistent moderate correlations in the .20's with the following six undesirable behavior traits: lack of interest in school, slovenliness, distractibility, fantastical lying, disobedience, and stealing and also one calculated for girls only, overinterest in the opposite sex. Among boys six notations showed moderate correlations in the .20's but low coefficients below .20 among girls: listlessness, daydreaming, destructiveness, truancy from home, unpopularity, and immoral home conditions. Among girls fifteen personality and conduct difficulties showed moderate correlations in the .20's but low coefficients below .20 among boys: disturbing influence in school, incorrigibility, defiant attitude, emotional instability, temper tantrums, temper display, quarrelsomeness, "spoiled child," crying spells, sensitiveness over some specific fact, question of change of personality, queer behavior, nail-biting, bad companions, and staff notation of unfavorable conduct prognosis.

There were three negative correlations with irresponsibility of moderate size in the  $-.20$ 's: among boys for feeble-minded sibling and among girls for retardation in school and vicious home conditions.

Among the six sex notations the only correlation of significant size with irresponsibility was for overinterest in the opposite sex,  $.20 \pm .06$  (calculated for girls only).

Among the seven physical or psychophysical disabilities the correlations with irresponsibility were very low or negligible.

Among the four home or familial notations there were two

moderate correlations in the .20's, the positive one of  $.23 \pm .06$  with immoral home conditions among boys and the negative one of  $-.27 \pm .08$  with vicious home conditions among girls.

CHAPTER XLVI

SLOVENLINESS AND CLEANLINESS

Slovenliness or marked lack of cleanliness or neatness in dress or appearance was noted among 337 of our 2,113 White boys (15.9 per cent) and among 205 of our 1,181 White girls (17.4 per cent). It was of only moderate importance or seriousness, its bi-serial correlations with the personality-total and conduct-total ranging from .22 to .30 (Table 89). With police arrest its tetrachoric r's for boys and girls respectively were only .19 ± .03 and -.02 ± .04.

## Other Correlations (Positive to Negative)

Absent-minded, .19 and -.03; Fighting, .18 and .17; Bad companions, .17 and .13; Unhappy, .17 and .09; Changeable moods, .16 and .08; Enuresis, .15 and .13; Emotional instability, .15 and .07; Sex denied entirely, .15 and .10; Stubborn, .14 and .17; Mental conflict, .14 and .15; Bossy, .13 and .16; Selfish, .13 and .06; Sullen, .13 and .03; Unpopular, .13 and .15; Discord between parents, .13 and .17; Follower, .13 and -.06; Grouped: dull, slow, etc., .13 and .15; Sulky, .12 and .13; Lack of initiative, .12 and .12; Distractable, .12 and .16; Leader, .12 and -.06; Seclusive, .11 and .09; Spoiled child, .11 and -.03; Preference for younger children as playmates, .11 and .06; Grouped: temper, etc., .11 and .11; Swearing (general), .10 (boys); Temper display, .10 and .04; Question of change of personality, .10 and .15; Inattentive in school, .09 and .13; Refusal to attend school, .09 and -.07; Crying spells, .09 and .11; Irritable, .09 and -.01; Slow, dull, .09 and .08; Object of teasing, .09 and .09; Popular, .09 and -.01; Exclusion from school, .08 and .13; Poor work in school, .08 and .12; Attractive manner, .08 and -.04; Question of encephalitis, .08 and -.03; Sex delinquency (coitus), .07 and .06; Oversuggestible, .07 and .18;

TABLE 89—Continued

Feeble-minded sibling, .07 and .07; Repressed, .06 and -.01; Victim of sex abuse .06 (girls); Apprehensive, .05 and .08; Restless in sleep, .05 and .14; Conduct prognosis bad, .05 and .09; Retardation in school, .05 and -.01; Former convulsions, .05 and .03; Brother in penal detention, .05 and .17; Inferiority feelings, .04 and .07; Stuttering, .03 (boys); Neurological defect, .04 and .07; Underweight, .04 and -.01; Grouped: sensitive or worrisome, etc., .02 and .07; Threatening violence, .02 (boys); Psychoneurotic, .02 and .05; Headaches, .02 and .14; Finicky food habits, .01 and .03; Bashful, .01 and .03; Question of hypophrenia, .01 and .08; Sensitive over specific fact, .01 and .06; Lues, .00 and -.05; Speech defect, -.01 and -.16; Sensitive (general), -.01 and .04; "Nervous," -.01 and .00; Worry over specific fact, -.05 and .02; Immoral home conditions, -.07 and .03; Vocational guidance, -.07 and -.14  
Omitted—Clean

Among boys its highest correlations, in the .30's, were with nail-biting and loitering or wandering, the corresponding correlation for girls being low, .12 and .07 respectively. Among girls four notations yielded substantial correlations in the .30's, the corresponding correlations for boys being moderate, ranging from .17 to .26: laziness, inefficiency in work, play, etc., stealing, and violence.

Slovenliness showed consistent moderate correlations in the .20's with fourteen conduct and personality problems: irresponsibility, excuse-forming attitude, incorrigibility, disturbing influence in school, leading others into bad conduct, rudeness, truancy from home, truancy from school, lying, swearing or bad language (undifferentiated), and the four notations for which only the boys' coefficients were calculated, running with a gang, smoking, teasing other children, and complaining of bad treatment by other children. Among boys six notations showed moderate correlations in the .20's but low coefficients below .20 among girls: contrariness, staying out late at night, destructiveness, restlessness, irregular sleep habits, and irregular attendance at school. Among girls sixteen notations showed moderate correlations in the .20's but low coefficients below .20 among boys: listlessness, lack of interest in school, daydreaming, depressed mood or spells, queer behavior, fantastical lying, boastful or "show-off" manner, egocentricity, quarrelsomeness, hatred or jealousy of sibling, disobedience, defiant attitude, temper tantrums, masturbation, over-interest in sex matters, and vicious home conditions.

Among the six sex notations there were three correlations

of moderate size in the .20's, all among girls: masturbation, overinterest in sex matters, and (calculated for girls only) overinterest in the opposite sex.

Among the seven physical or psychophysical notations all correlations were low or negligible.

Among the four home or familial notations the only correlation of moderate size with slovenliness was with vicious (not "immoral") home conditions, among girls,  $.22 \pm .06$ .

Clean, neat habits or appearance was one of the few "desirable" behavior traits which were noted frequently enough in our data to justify correlational treatment. It was noted among 318, or 15.0 per cent, of our boys and among 171, or 14.5 per cent, of our girls. Its correlations with our three criteria of seriousness or "ominousness" were all low or negligible.

Attractive manner yielded substantial correlations in the .30's among both sexes (Table 90). Worry over some specific fact among girls also yielded the substantial correlation of  $.34 \pm .07$  with a moderate coefficient of  $.24 \pm .05$  among boys.

Sensitiveness or worrisomeness (undifferentiated) and sensitiveness in general showed moderate correlations in the .20's among both sexes. Three notations—boastful or "show-off" manner, sensitiveness over some specific fact, and daydreaming—among boys showed moderate correlations in the .20's but among girls low coefficients below .20. Six notations among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: popularity, sex misbehavior denied entirely, repressed manner, changeable moods or attitudes, irregular sleep habits, and refusal to attend school.

Clean habits showed negative correlations of moderate size in the -.20's with three notations: among boys with retardation in school and among girls with feeble-minded sibling and loitering or wandering.

Among the six sex notations the seven physical or psychophysical disabilities and the four home or familial notations the only significant correlation with clean habits was with sex misbehavior denied entirely among girls,  $.25 \pm .07$ . All other correlations in these fields were low or negligible, ranging from  $-.16$  to  $.18$ .

Fantastical lying, .18 and .06; Sex delinquency (coitus), .18 and -.06; Lack of initiative, .18 and .06; "Nervous," .15 and .01; Irregular attendance at school, .15 and .12; Bashful, .15 and .03; Inferiority feelings, .14 and .10; Lazy, .14 and .04; Hatred or jealousy of sibling, .13 and -.01; Complaining of bad treatment by other children, .12 (boys); Unpopular, .12 and -.08; Masturbation, .12 and .08; Bossy, .11 and .18; Finicky food habits, .11 and .18; Mental conflict, .11 and .10; Grouped: depressed, etc., .10 and .13; Grouped: "nervous," etc., .10 and .08; Seclusive, .10 and .08; Depressed, .10 and .14; Inattentive in school, .10 and -.08; Teasing other children, .09 (boys); Smoking, .09 (boys); Irritable, .09 and .07; Unhappy, .09 and .09; Leader, .09 and .07; Speech defect, .08 and .04; Headaches, .08 and -.01; Egocentric, .08 and .03; Temper display, .08 and .06; Sullen, .08 and -.03; Selfish, .08 and .12; Rude, .07 and .09; Immoral home conditions, .07 and -.02; Discord between parents, .07 and .02; Grouped: egocentric, etc., .07 and .05; Grouped: lack of interest in school, etc., .07 and .05; Victim of sex abuse, .07 (girls); Exclusion from school, .06 and -.01; Spoiled child, .06 and .06; Apprehensive, .06 and .11; Bad companions, .06 and -.06; Sulky, .06 and .14; Stealing, .06 and

TABLE 90—Continued

-.11; Defiant, .06 and -.02; Lack of interest in school, .05 and -.04; Leading others into bad conduct, .05 and .07; Question of change of personality, .05 and .02; Restless, .05 and .03; Restless in sleep, .05 and .08; Former convulsions, .05 and .01; Grouped: temper, etc., .05 and .12; Poor work in school, .04 and -.06; Vocational guidance, .04 and .19; Psychoneurotic, .04 and .06; Overinterest in sex matters, .04 and .00; Stubborn, .04 and .12; Destructive, .04 and -.04; Contrary, .04 and .10; Truancy from school, .03 and -.16; Crying spells, .03 and .06; Excuse-forming, .03 and .06; Neurological defect, .03 and .11; Lues, .03 and .06; Grouped: swearing, etc., .02 and -.03; Absent-minded, .02 and .16; Gang, .02 (boys); Disturbing influence in school, .01 and -.02; Violence, .01 and .06; Oversuggestible, .01 and -.02; Grouped: disobedient, etc., .01 and .00; Incorrigible, -.00 and -.07; Lying, -.00 and -.00; Temper tantrums, -.00 and .10; Vicious home conditions, -.01 and .00; Staying out late at night, -.01 and -.07; Nail-biting, -.01 and .04; Enuresis, -.01 and .12; Inefficient in work, play, etc., -.02 and .06; Truancy from home, -.02 and .16; Listless, -.02 and .13; Object of teasing, -.02 and -.09; Grouped: dull, slow, etc., -.03 and .07; Follower, -.03 and .07; Conduct prognosis bad, -.03 and -.04; Threatening violence, -.03 (boys); Quarrelsome, -.04 and -.03; Stuttering, -.04 (boys); Preference for younger children, -.04 and .07; Grouped: fighting, etc., -.04 and .05; Question of encephalitis, -.05 and .17; Distractible, -.05 and .09; Disobedient, -.05 and -.06; Swearing (general), -.06 (boys); Irresponsible, -.07 and .06; Overinterest in opposite sex, -.07 (girls); Fighting, -.08 and .12; Brother in penal detention, -.08 and -.16; Queer, -.09 and .07; Emotional instability, -.10 and .07; Slow, dull, -.11 and .06; Question of hypophrenia, -.12 and -.17; Underweight, -.15 and .13

Omitted—Slovenly

In general it may be said that clean habits showed almost no association with undesirable conduct manifestations but did show a few moderate correlations with personality difficulties. It appeared to be positively associated with such desirable traits as attractive manner and popularity.

A comparison of the corresponding correlations for the presumably antithetical notations slovenliness (Table 89) and clean habits (Table 90) shows again the curious statistical phenomenon that many of the coefficients for these antithetical pairs of traits were not of opposite sign and of similar magnitude, as would be expected if strictly objectively measurable traits were being used, but were often of the same sign (though of different magnitude). Among the 119 pairs of corresponding coefficients for the boys in Table 89 (slovenliness) and Table 90 (clean habits) there were 78 pairs of like sign and only 41 of unlike sign. Among 114 pairs of girls' coefficients there were 71 pairs of like sign and only 43 of unlike sign. The intercolumnar correlations (Pearson's product-moment) were  $-.11 \pm .06$  for boys and  $-.27 \pm .06$  for girls.

(A discussion and attempted explanation of this phenomenon may be found in I, 134-35 and 249-50, and in this volume, p. 45, and in the concluding paragraphs of chaps. xx, xxv, and liii.)

## CHAPTER XLVII

### LACK OF INTEREST OR INATTENTIVENESS IN SCHOOL STUDIES, EMPLOYMENT, ETC.

To distinguish between the notations lack of interest in school or inattentiveness in school studies, employment, etc., and the similar notation inattentiveness in school was frequently not easy in the perusal of the actual case records, and it is probable that these rubrics have been inadequately differentiated in our original indexing of the data. "Lack of interest" was intended to denote a more fundamental attitude in the patient, while "inattentiveness" was intended to designate a more superficial overt behavior in the classroom. The bi-serial correlations for each rubric with the personality-total and conduct-total were only moderate, ranging from .18 to .32. Their tetrachoric correlations with police arrest were low with the exception of the moderate coefficient of  $.26 \pm .05$  among girls for inattentiveness in school.

Lack of interest in school was noted among 279 of our 2,113 White boys (13.2 per cent) and among 107 of our 1,181 White girls (9.1 per cent). Among both sexes its largest correlations were with poor work in school, the respective coefficients for boys and girls being  $.32 \pm .03$  and  $.42 \pm .04$  (Table 91). Disturbing influence in school yielded the substantial correlations of  $.31 \pm .03$  and  $.29 \pm .06$  among boys and girls respectively. Six behavior traits among girls also yielded substantial correlations in the .30's but low positive coefficients ranging from .10 to .21 among boys: refusal to attend school, restlessness, question of change of personality, sullenness, fighting, and swearing or bad language (undifferentiated).

Lack of interest in school showed consistent moderate correlations in the .20's with eight behavior difficulties: irresponsibility, laziness, inefficiency in work, play, etc., truancy from school, disobedience, rudeness, and (calculated for boys only) threatening violence and (calculated for girls only) overinterest in the opposite sex. Nine behavior notations among boys showed

## Other Correlations (Positive to Negative)

Smoking, .19 (boys); Daydreaming, .19 and .19; Complaining of bad treatment by other children, .19 (boys); Egocentric, .18 and .06; Inferiority feelings, .18 and .11; Preference for younger children, .18 and .17; Grouped: egocentric, etc., .18 and .12; Gang, .17 (boys); Lack of initiative, .17 and .06; Sensitive (general), .17 and .02; Grouped: sensitive or worrisome, etc., .17 and .16; Teasing other children, .16 (boys); Quarrelsome, .16 and .14; Seclusive, .16 and .12; Grouped: depressed, etc., .16 and .13; Truancy from home, .15 and .11; Fantastical lying, .14 and .15; Listless, .14 and .16; Sulky, .13 and .05; Irritable, .13 and .14; Follower, .13 and .14; Destructive, .12 and .12; Incurable, .12 and .14; Crying spells, .12 and .10; Depressed, .12 and .07; Irregular sleep habits, .12 and .17; "Nervous," .12 and .12; Spoiled child, .11 and .13; Sex denied entirely, .11 and .04; Grouped: temper, etc., .11 and .17; Excuse-forming, .10 and .17; Queer, .10 and .18; Headaches, .10 and -.05; Bashful, .09 and .05; Grouped: dull, slow, etc., .09 and .17; Bossy, .08 and .18; Nail-biting, .08 and .08; Selfish, .08 and .01; Stubborn, .08 and .16; Swearing (general), .08 (boys); Worry over specific fact, .08 and .01; Question of encephalitis, .08 and .11; Discord between parents, .08 and -.03; Oversuggestible, .07 and .08; Vocational guidance, .07 and .01; Irregular attendance at school, .07 and .19; Masturbation, .06 and .10; Enuresis, .05 and .04; Restless in sleep, .05 and .08; Emotional instability, .05 and .08; Clean, .05 and -.04; Underweight, .03 and -.03; Absent-minded, .02 and .08; Victim of sex abuse, .02 (girls); Attractive manner, .02 and .15; Vicious home conditions, .01 and .18; Repressed, .01 and .12; Conduct prognosis bad, .00 and .16; Speech defect, .00 and .13; Neurological defect, -.00 and .12; Popular, -.01 and -.04; Psychoneurotic, -.01 and .05; Temper display, -.01 and .00; Finicky food habits, -.01 and .09; Brother in penal detention, -.02 and -.08; Question of hypophrenia, -.02 and .04; Slow, dull, -.02 and .13; Former convulsions, -.04 and .01; Retardation in school, -.06 and -.04; Lues, -.07 and .11; Feeble-minded sibling, -.09 and -.08; Overinterest in sex matters, -.09 and .12; Immoral home conditions, -.11 and .08; Stuttering, -.12 (boys); Sex delinquency (coitus), -.13 and .10

Omitted—Grouped: lack of interest in school, etc.

moderate correlations in the .20's but low coefficients below .20 among girls: loitering or wandering, bad companions, hatred or jealousy of sibling, boastful or "show-off" manner, "nervousness" or restlessness (undifferentiated), unpopularity, mental conflict, unhappiness, and "leader." Sixteen undesirable notations among girls showed moderate correlations in the .20's but low coefficients below .20 among boys: inattentiveness in school, distractibility, slovenliness, changeable moods or attitudes, contrariness,

defiant attitude, temper tantrums, violence, stealing, staying out late at night, lying, leading others into bad conduct, exclusion from school, object of teasing by other children, apprehensiveness, and sensitiveness over some specific fact.

Among the six sex notations the only one of moderate size was with overinterest in the opposite sex among girls,  $.22 \pm .05$ , the corresponding boys' coefficient being omitted because of the paucity of boys' cases. All other correlations in the sphere of sex, as well as for the seven physical notations and the four familial notations, were low or negligible, ranging from  $-.12$  to  $.18$ .

Inattentiveness in school was noted among 223 boys (10.6 per cent) and among 81 girls (6.9 per cent).

Its more considerable correlations were as follows. Disturbing influence in school yielded substantial correlations in the .30's among both sexes (Table 92). Lack of initiative among boys yielded the substantial coefficient of  $.39 \pm .04$ , but the negligible one of  $.09$  among girls. Victim of sex abuse by older child or person among girls also yielded the substantial correlation of  $.30 \pm .06$ , the boys' correlations being omitted because of paucity of boys' cases. Disobedience and restlessness among girls yielded substantial correlations in the .30's with moderate coefficients in the .20's among boys. Excuse-forming attitude, distractibility, and overinterest in sex matters among girls similarly yielded substantial correlations in the .30's but low coefficients below  $.20$  among boys.

Inattentiveness in school showed consistent moderate correlations in the .20's with the following eight undesirable notations: poor work in school, laziness, lying, destructiveness, unpopularity, masturbation, exclusion from school, and (calculated for boys only) teasing other children. Six personality and conduct problems among boys showed moderate correlations in the .20's but among girls low positive coefficients below  $.20$ : daydreaming, inefficiency in work, play, etc., rudeness, boastful or "show-off" manner, defiant attitude, and fighting. Among girls a list of seventeen miscellaneous behavior traits showed moderate correlations in the .20's but low positive coefficients below  $.20$  among boys: lack of interest in school, listlessness, "spoiled child," finicky food habits, stubbornness, quarrelsomeness, selfishness,

Conduct prognosis bad.....	-.04	-.21 ± .08

## Other Correlations (Positive to Negative)

Incorrigible, .19 and .19; Truancy from school, .18 and .16; Hatred or jealousy of sibling, .18 and .11; Complaining of bad treatment by other children, .17 (boys); Overinterest in opposite sex, .16 (girls); Changeable moods, .15 and .09; Queer, .15 and -.04; Egocentric, .14 and .13; Attractive manner, .14 and .02; Bossy, .13 and .17; Irresponsible, .13 and .09; Absent-minded, .13 and .17; Worry over specific fact, .13 and .18; Staying out late at night, .12 and .18; Seclusive, .12 and .11; Nail-biting, .11 and .11; Leading others into bad conduct, .10 and -.12; Smoking, .10 (boys); Truancy from home, .10 and .07; Clean, .10 and -.08; Contrary, .09 and .03; Slovenly, .09 and .13; Sulky, .09 and .01; Temper display, .09 and .01; Violence, .09 and .18; Headaches, .09 and .15; Refusal to attend school, .08 and -.08; Inferiority feelings, .08 and .15; Popular, .08 and .05; Gang, .07 (boys); Crying spells, .07 and -.01; Question of hypochondria, .07 and -.15; Grouped: dull, slow, etc., .07 and .03; Sullen, .06 and .07; "Nervous," .06 and .19; Irregular attendance at school, .06 and -.03; Discord between parents, .06 and .01; Vicious home conditions, .06 and -.11; Grouped: temper, etc., .06 and .14; Enuresis, .05 and .09; Former convulsions, .05 and -.05; Loitering, .04 and .14; Irregular sleep habits, .04 and .03; Neurological defect, .04 and -.03; Grouped: sensitive or worrisome, etc., .04 and .06; Apprehensive, .03 and .13; Repressed, .03 and .16; Bashful, .02 and -.02; Psychoneurotic, .02 and -.02; Swearing (general), .01 (boys); Sex delinquency (coitus), .01 and -.04; Question of change of personality, .01 and .08; Slow, dull, .01 and -.08; Sensitive (general), .01 and .04; Underweight, .01 and .02; Vocational guidance, .01 and .06; Oversuggestible, .00 and .02; Sensitive over specific fact, -.00 and .09; Irritable, -.00 and .18; Depressed, -.02 and .08; Brother in penal detention, -.03 and -.00; Emotional instability, -.03 and -.04; Follower, -.04 and .11; Grouped: depressed, etc., -.05 and .04; Immoral home conditions, -.05 and -.09; Threatening violence, -.05 (boys); Lues, -.06 and -.17; Stuttering, -.06 (boys); Retardation in school, -.08 and -.10; Question of encephalitis, -.09 and .18; Unhappy, -.10 and -.00; Speech defect, -.11 and .00

Omitted—Grouped: lack of interest in school, etc.

temper tantrums, swearing or bad language (undifferentiated), restlessness in sleep, stealing, bad companions, fantastical lying, mental conflict, object of teasing by other children, preference for younger children as playmates, and "leader."

Three notations showed moderate negative correlations ranging from  $-.21$  to  $-.28$ : feeble-minded sibling among both sexes, and sex misbehavior denied entirely and staff notation of unfavorable conduct prognosis among girls.

Among the six sex notations there were several correlation coefficients of statistically significant size in the .20's and .30's: masturbation among both sexes, overinterest in sex matters among girls, and victim of sex abuse by older child or person (calculated for girls only). Sex misbehavior denied entirely among girls showed the negative correlation of  $-.24 \pm .08$ .

Among the seven physical or psychophysical disabilities and among the four home or familial notations, all correlations with inattentiveness in school were low or negligible, ranging from  $-.17$  to  $.18$ .

When the cases falling under the rubrics lack of interest in school or school studies, employment, etc., and inattentiveness in school were combined into a broad grouping,<sup>1</sup> there were 467 such cases, or 22.1 per cent, among our 2,113 White boys and 172 cases, or 14.6 per cent, among our 1,181 White girls. An examination of the resulting correlation coefficients as shown in Table 93 with the corresponding correlations in the two preceding chapters shows that the effect of combining these notations was in general to increase the size of the resulting coefficients. The fact of this increase in the resulting correlations indicates a close similarity between the two rubrics and suggests the likelihood that the two component notations overlapped to such a degree that one should not have attempted to set up more than one category in the original indexing of this material. We may, therefore, summarize the correlations in Table 93 in the following brief manner.

The highest correlations, ranging from  $.32$  to  $.41$  with the broader grouping lack of interest or inattentiveness in school studies or employment (undifferentiated), were with the two notations disturbing influence in school and poor work in school.

Fifteen undesirable notations yielded moderate to substantial correlations in the .20's and .30's among both sexes: lazi-

---

<sup>1</sup>The reasons for this broader grouping were given in I, 44; see p. 86, Table 13, Item H.

## Other Correlations (Positive to Negative)

Complaining of bad treatment by other children, .19 (boys); Leader, .18 and .15; Smoking, .18 (boys); Loitering, .18 and .10; Gang, .17 (boys); Spoiled child, .17 and .19; Leading others into bad conduct, .16 and .10; Sulky, .15 and .03; Truancy from home, .15 and .11; Queer, .15 and .15; Inferiority feelings, .14 and .13; Worry over specific fact, .14 and .10; Seclusive, .14 and .15; Selfish, .14 and .14; Grouped: sensitive or worrisome, etc., .14 and .12; Crying spells, .13 and .09; Lack of initiative, .13 and .03; Sensitive over specific fact, .12 and .18; "Nervous," .12 and .15; Threatening violence, .11 (boys); Sensitive (general), .11 and .04; Unhappy, .11 and .14; Irregular sleep habits, .10 and .17; Depressed, .10 and .09; Absent-minded, .10 and .15; Grouped: dull, slow, etc., .10 and .10; Grouped: depressed, etc., .10 and .13; Headaches, .10 and .04; Irregular attendance at school, .10 and .09; Changeable moods, .09 and .18; Follower, .08 and .11; Discord between parents, .08 and -.02; Vocational guidance, .08 and .02; Attractive manner, .08 and .09; Swearing (general), .07 (boys); Oversuggestible, .07 and .04; Restless in sleep, .07 and .17; Clean, .07 and .05; Popular, .06 and .03; Bashful, .06 and .04; Finicky food habits, .05 and .18; Nail-biting, .04 and .08; Enuresis, .04 and .09; Vicious home conditions, .04 and .09; Sex denied entirely, .03 and -.04; Underweight, .03 and -.00; Emotional instability, .03 and .07; Neurological defect, .03 and .09; Temper display, .03 and .01; Repressed, .02 and .17; Psychoneurotic, .02 and .02; Slow, dull, .00 and .03; Former convulsions, -.00 and .01; Conduct prognosis bad, -.01 and .08; Brother in penal detention, -.02 and -.05; Lues, -.05 and .04; Question of hypophrenia, -.05 and -.03; Retardation in school, -.05 and -.07; Sex delinquency (coitus), -.09 and .06; Speech defect, -.09 and .01; Immoral home conditions, -.09 and .03; Stuttering, -.11 (boys); Feeble-minded sibling, -.17 and -.13

Omitted—Inattentive in school; Lack of interest in school

ness, inefficiency in work, play, etc., irresponsibility, truancy from school, bad companions, exclusion from school, disobedience, stealing, defiant attitude, destructiveness, fighting, rudeness, restlessness, lying, and unpopularity and (calculated for boys

only) teasing other children and (calculated for girls only) overinterest in opposite sex and victim of sex abuse by older child or person. Among boys daydreaming, boastful or "show-off" manner, egocentricity, and hatred or jealousy of sibling showed moderate correlations in the .20's but low positive coefficients below .20 among girls. Twenty-five personality and conduct problems among girls showed moderate to substantial correlations in the .20's and .30's but low positive correlations below .20 among boys: refusal to attend school, stubbornness, incurability, contrariness, violence, quarrelsomeness, staying out late at night, distractibility, listlessness, slovenliness, question of change of personality, mental conflict, apprehensiveness, excuse-forming attitude, temper tantrums, irritable temperament, swearing or bad language (undifferentiated), fantastical lying, sullenness, bossy manner, object of teasing by other children, preference for younger children as playmates, masturbation, overinterest in sex matters, and question or diagnosis of encephalitis.

Among the six sex notations there were four positive coefficients of moderate size in the .20's, all among girls: overinterest in sex matters, masturbation, and two for which only the girls' correlations were calculated—overinterest in the opposite sex and victim of sex abuse by older child or person.

Among the seven physical or psychophysical notations the only correlation of moderate size was the statistically questionable one of .20 + .07 with question or diagnosis of encephalitis among girls.

Among the four home or familial notations all correlations in this chapter were low or negligible.

CHAPTER XLVIII

DISTURBING INFLUENCE IN SCHOOL

Disturbing influence or marked mischievousness in school was noted among 348, or 16.5 per cent, of our 2,113 White boys and among 89, or 7.5 per cent, of our 1,181 White girls. It is a matter of common observation that girls adjust their conduct better in school routine than do the boys. With the factor of chronological age, its bi-serial correlation among girls was negative and of moderate size,  $-.24 \pm .04$ , and among boys negligible,  $-.06$  (Table 9, p. 128). With intelligence quotient (IQ) its bi-serial correlations were negligible,  $-.01$  and  $.04$  (Table 10, p. 130).

Its bi-serial correlations with the conduct-total among both sexes and with personality-total among girls were large, ranging from  $.46$  to  $.52$  (Table 94). Among boys the correlation

## Other Correlations (Positive to Negative)

Refusal to attend school, .19 and .08; Sullen, .19 and .17; Inferiority feelings, .19 and .18; Overinterest in opposite sex, .19 (girls); Staying out late at night, .17 and .06; Temper display, .17 and .12; Leader, .17 and .18; Gang, .16 (boys); Irritable, .16 and .19; Oversuggestible, .15 and .04; Mental conflict, .14 and .10; Selfish, .13 and .12; Irregular sleep habits, .13 and .16; Masturbation, .12 and .12; Former convulsions, .12 and .08; Vicious home conditions, .11 and .13; Depressed, .10 and .13; Unhappy, .10 and .10; Finicky food habits, .09 and .08; Grouped: depressed, etc., .09 and .13; Attractive manner, .08 and .09; Sex denied entirely, .07 and .03; Victim of sex abuse, .07 (girls); Hatred or jealousy of sibling, .06 and -.02; Headaches, .06 and .14; Retardation in school, .05 and -.02; Irregular attendance at school, .05 and -.00; Discord between parents, .05 and -.01; Preference for younger children, .04 and .16; Absent-minded, .03 and .08; Sensitive (general), .03 and .06; Follower, .03 and .01; Popular, .02 and .12; Clean, .01 and -.02; Grouped: sensitive or worrisome, etc., .01 and .17; Worry over specific fact, -.00 and .17; Sensitive over specific fact, -.00 and .10; Question of hypophrenia, -.01 and .12; Listless, -.02 and .10; Apprehensive, -.02 and .19; Underweight, -.03 and .01; Seclusive, -.03 and -.01; Brother in penal detention, -.04 and .06; Immoral home conditions, -.06 and -.12; Vocational guidance, -.08 and .03; Repressed, -.08 and .01; Stuttering, -.09 (boys); Sex delinquency (coitus), -.09 and .02; Grouped: dull, slow, etc., -.11 and .04; Slow, -.11 and .05; Bashful, -.12 and -.06; Psychoneurotic, -.16 and -.04

with personality-total was only moderate, .26 ± .02. With the police-arrest criterion of seriousness, the boys' tetrachoric correlation was only moderate, .23 ± .03, and the girls' coefficient negligible, .04 ± .07.

Its largest correlations were for exclusion from school with the coefficients of .51 among both sexes. Boastful or "show-off" manner also yielded large coefficients of .51 ± .03 and .44 ± .06 for boys and girls respectively. Unpopularity and (calculated for boys only) teasing other children yielded large correlations in the .40's. Rudeness yielded respective coefficients of .40 ± .03 and .35 ± .05 among boys and girls. The following six

conduct difficulties among girls yielded large correlations in the .40's and among boys substantial coefficients in the .30's: fighting, violence, incorrigibility, disobedience, swearing or bad language (undifferentiated), and lying. Four behavior traits among girls similarly yielded large correlations in the .40's and moderate coefficients ranging from .18 to .28 among boys: defiant attitude, temper tantrums, distractibility, and object of teasing by other children.

Four conduct problems yielded substantial correlations in the .30's among both sexes: inattentiveness in school, quarrelsomeness, destructiveness, and fantastical lying. Four undesirable behavior traits among boys yielded substantial correlations in the .30's and moderate coefficients ranging from .19 to .29 among girls: lack of interest in school, leading others into bad conduct, contrariness, and restlessness. Three notations among girls yielded substantial correlations in the .30's and among boys moderate correlations in the .20's: poor work in school, stubbornness, and excuse-forming attitude. An additional seven miscellaneous conduct and personality problems among girls yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: truancy from school, daydreaming, question of change of personality, queer behavior, "nervousness," restlessness in sleep, and question or diagnosis of encephalitis.

Nine conduct and personality difficulties showed consistently moderate correlations in the .20's: bossy manner, egocentricity, "spoiled child," slovenliness, stealing, and the four conduct problems for which only the boys' coefficients were calculated: swearing in general, smoking, threatening violence, and complaining of bad treatment by other children. Four conduct difficulties among boys showed moderate coefficients in the .20's but low coefficients ranging from .10 to .18 among girls: truancy from home, sulkiness, laziness, and loitering or wandering. Among girls thirteen miscellaneous case-record notations showed moderate correlations in the .20's but low or negligible coefficients below .20 among boys: emotional instability, changeable moods or attitudes, crying spells, irresponsibility, inefficiency in work, play, etc., bad companions, overinterest in sex matters, enuresis, nail-biting, neurological defect (unspecified), lues, speech defect (other than stuttering), and staff notation of unfavorable conduct prognosis.

Two notations showed moderate negative correlations in the -.20's with disturbing influence in school, both among boys: lack of initiative and feeble-minded sibling.

Among the six sex notations all correlations were low except the doubtfully significant one of  $.20 \pm .07$  with overinterest in sex matters among girls.

Among the seven physical or psychophysical notations there were five coefficients of moderate size ranging from .20 to .31, all among girls: question of diagnosis of encephalitis, neurological defect (unspecified), lues, enuresis, and speech defect (other than stuttering).

Among the four home or familial notations all correlations with disturbing influence in school were low or negligible.

CHAPTER XLIX

RUDENESS

Rudeness, impertinence, impudence, etc., toward adults was a fairly frequently appearing notation among our cases, the incidence being about 15 per cent of both boys and girls in this study. Its bi-serial correlations with the conduct-total were large, .48 + .02 and .55 ± .02 among boys and girls respectively (Table 95).

TABLE 95

## Other Correlations (Positive to Negative)

Nail-biting, .17 and .12; Irresponsible, .15 and .15; Refusal to attend school, .15 and .13; "Nervous," .15 and .05; Restless in sleep, .14 and .14; Conduct prognosis bad, .14 and .13; Sensitive over specific fact, .13 and .01; Discord between parents, .13 and .15; Sex denied entirely, .12 and -.09; Loitering, .11 and .02; Sex delinquency (coitus), .11 and .06; Mental conflict, .11 and .12; Poor work in school, .11 and .09; Vicious home conditions, .11 and .13; Leader, .10 and .07; Enuresis, .09 and .07; Repressed, .09 and .03; Attractive manner, .09 and .06; Grouped: sensitive or worrisome, etc., .08 and .10; Clean, .07 and .09; Immoral home conditions, .07 and .10; Psychoneurotic, .06 and .13; Distractible, .06 and .11; Seclusive, .06 and .05; Irregular attendance at school, .06 and .01; Apprehensive, .05 and .14; Object of teasing, .05 and .10; Worry over specific fact, .05 and .07; Headaches, .05 and .18; Former convulsions, .05 and .04; Victim of sex abuse, .05 (girls); Brother in penal detention, .05 and .11; Popular, .04 and .04; Absent-minded, .03 and .08; Follower, .03 and -.09; Listless, .02 and .05; Neurological defect, .02 and .01; Sensitive (general), .00 and .16; Lues, .00 and -.00; Vocational guidance, .00 and -.06; Underweight, -.01 and .04; Preference for younger children, -.01 and .00; Oversuggestible, -.01 and -.03; Grouped: dull, slow, etc., -.07 and -.08; Question of hypophrenia, -.07 and -.12; Lack of initiative, -.07 and -.13; Slow, dull, -.09 and -.12; Retardation in school, -.11 and -.11; Feeble-minded sibling, -.12 and .17; Stuttering, -.19 (boys)

Its corresponding correlations with the personality-total were substantial,  $.32 \pm .02$  and  $.39 \pm .03$ . With the police-arrest criterion of "juvenile delinquency" its tetrachoric correlations were only moderate,  $.19 \pm .03$  and  $.20 \pm .04$ .

Its highest correlations among both sexes ranged from .44 to .54 for the four conduct problems, defiant attitude, disobedience, incorrigibility, and swearing or bad language (undifferentiated). Contrariness and disturbing influence in school among boys yielded correlations in the .40's and among girls in the .30's. Three conduct problems among girls similarly yielded large correlations in the .40's with similar substantial coefficients in the .30's among boys: boastful or "show-off" manner, fighting, and temper tantrums. An additional three conduct difficulties among girls yielded large correlations in the .40's but moderate coefficients in the .20's among boys: sullenness, quarrelsomeness, and leading others into bad conduct.

Six unfavorable notations consistently yielded substantial correlations in the .30's: violence, egocentricity, exclusion from school, and the two notations for which only the boys' coefficients were calculated—teasing other children and swearing in general—and (calculated for girls only) overinterest in the opposite sex.

Three conduct and personality difficulties among boys yielded substantial correlations in the .30's with moderate correlations in the .20's among girls: destructiveness, hatred or jealousy of sibling, and restlessness. Among girls five behavior traits yielded substantial correlations in the .30's with moderate coefficients in the .20's among boys: stubbornness, irritable temperament, changeable moods or attitudes, lying, and unpopularity. Five additional behavior traits among girls yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: temper display, excuse-forming attitude, daydreaming, queer behavior and (calculated for girls only) overinterest in sex matters.

Rudeness showed consistent moderate correlations in the .20's with fourteen undesirable conduct and personality manifestations: "spoiled child," sulkiness, laziness, slovenliness, truancy from school, staying out late at night, lack of interest in school, stealing, fantastical lying, and the four traits for which only the boys' coefficients were calculated—threatening violence, running with a gang, smoking, and complaining of bad treatment by other children. Seven personality and conduct difficulties showed moderate correlations in the .20's among boys but low positive coefficients below .20 among girls: bossy manner, selfishness, bad companions, inattentiveness in school, depressed mood or spells, inferiority feelings, and irregular sleep habits. Among girls eight miscellaneous notations showed moderate correlations in the .20's but low coefficients below .20 among boys: emotional instability, question of change of personality, unhappiness, crying spells, inefficiency in work, play, etc., finicky food habits, mas turbation, and question or diagnosis of encephalitis.

Rudeness among girls showed negative correlations of moderate size in the -.20's with bashfulness and speech defect (other than stuttering).

Among the six sex notations there were three moderate or substantial correlations ranging from .29 to .33, all among girls: masturbation, overinterest in sex matters, and (calculated for girls only) overinterest in the opposite sex.

Among the seven physical or psychophysical disabilities there were two correlations of moderate size, both among girls: the positive coefficient of .24 + .07 with question or diagnosis

of encephalitis and the negative one of  $-.26 \pm .05$  with speech defect.

Among the four home or familial notations all correlations were low or negligible, ranging from .05 to .15.

## CHAPTER I

### SEX NOTATIONS

A miscellaneous group of six sex notations which appeared with sufficient frequency in our case-record material to justify correlational treatment is discussed in this chapter. Although in the original indexing of our total 5,000 cases there were a large variety of sex items (as listed in I, 56, Table 2; 69-71, Table 4; and 72, Table 5), most of these items occurred so seldom that adequate statistical treatment was not feasible. In addition to the six notations to be discussed in Tables 96-101, there were another six categories (sex attack on person of opposite sex, "annoying" girls, mutual masturbation with child of the same sex, homosexual practices with child of same age, passive pederasty, and exhibitionism or "indecent exposure") for which correlations could be calculated among boys, but only with the personality-total, conduct-total, police arrest, chronological age, and intelligence quotient (this volume, Tables 6-10 inclusive).

Sex delinquency, which in our study has been rigidly defined as "coitus or copulation with a person of the opposite sex," was noted among only 70 of our 2,113 White boys, or 3.3 per cent, but among 218 of our 1,181 White girls, or 18.5 per cent. Among girls its tetrachoric correlation of  $.76 \pm .02$  with the police-arrest criterion of "juvenile delinquency" was unusually high, in fact, conspicuously the largest correlation with police arrest found among all our correlations (Table 96). All other correlations among both sexes with our three criteria of seriousness or "ominousness" were consistently low, the coefficients ranging from .08 to .18.

Its largest correlations among both sexes were in the .40's with the two sex notations, overinterest in sex matters and masturbation. Victim of sex abuse by older child or person among girls yielded the large correlation of  $.44 \pm .04$ , the boys' coefficient not being calculated because of the paucity of boys' cases. Staff

Popular, .18 and -.01; Clean, .18 and -.06; Worry over specific fact, .18 and .15; Psychoneurotic, .17 and -.05; Grouped: fighting, etc., .17 and .09; Depressed, .16 and .01; Inferiority feelings, .15 and -.09; Smoking, .14 (boys); Grouped: egocentric, etc., .14 and .03; Selfish, .13 and -.13; Violence, .13 and .14; Sensitive over specific fact, .13 and .01; Grouped: depressed, etc., .13 and .03; Fantastical lying, .12 and .01; Rude, .11 and .06; Grouped: sensitive or worrisome, etc., .11 and -.01; Gang, .09 (boys); Fighting, .08 and .09; Threatening violence, .08 (boys); Preference for younger children, .08 and -.13; Unhappy, .08 and .01; Follower, .08 and .17; Egocentric, .08 and .07; Nail-biting, .07 and .03; Slovenly, .07 and .06; Sullen, .07 and .09; Swearing (general), .07 (boys); Exclusion from school, .07 and .18; Former convulsions, .07 and -.14; Brother in penal detention, .07 and .10; Inefficient in work, play, etc., .06 and .01; Discord between parents, .06 and .06; Vicious home conditions, .06 and .19; Crying spells, .05 and -.05; Repressed, .05 and -.08; Leader, .05 and -.04; Refusal to attend school, .04 and -.01; Irregular sleep habits, .04 and -.15; Queer, .04 and .17; Emotional instability, .04 and .17; Question of change of personality, .03 and .13; Boastful, "show-off," .02 and .10; Listless, .02 and .01; Defiant, .01 and .07; Inattentive in school, .01 and -.04; Teasing other children, .01 (boys); Contrary, .00 and .07; Temper display, -.00 and -.09; Feeble-minded sibling, -.00 and .11; Changeable moods, -.00 and .03; Object of teasing, -.01 and -.08; Question of hypochondria, -.01 and -.08; Grouped: temper, etc., -.01 and -.09; Enuresis, -.01 and .05; Sensitive (general), -.02 and -.18; Headaches, -.02 and -.08; Finicky food habits, -.03 and -.04; Quarrelsome, -.03 and -.01; Complaining of bad treatment by other children, -.03 (boys); Excuse-forming, -.04 and .09; Distractible, -.04 and .05; Apprehensive, -.05 and -.00; Destructive, -.06 and .02; Temper tantrums, -.06 and .08; Spoiled child, -.06 and -.08; Hatred or jealousy of sibling, -.07 and -.09; Disturbing influence in school, -.09 and .02; Stubborn, -.09 and .12; Slow, dull, -.09 and .01; Restless, -.09 and .09; Seclusive, -.09 and -.04; Unpopular, -.09 and .18; Grouped: lack of interest in school, -.09 and .06; Speech defect, -.10 and -.09; Poor work in school, -.11 and -.19; Retardation in school, -.11 and -.02; Grouped: dull, slow, etc., -.11 and -.15; Lack of interest in school, -.13 and .10; Bossy, -.14 and .01; Irresponsible, -.14 and .11; Attractive manner, -.14 and -.13; Absent-minded, -.16 and -.03

Omitted—Sex denied entirely

notation of unfavorable conduct prognosis among girls yielded the large correlation of  $.48 \pm .05$ , and a substantial coefficient of  $.32 \pm .08$  among boys. Three additional notations among girls yielded large correlations in the .40's but low positive coefficients ranging from .10 to .16 among boys: truancy from home, staying out late at night, and leading others into bad conduct.

Overinterest in the opposite sex among girls yielded the substantial correlation of  $.38 \pm .04$ , the boys' coefficient not being calculated because of fewness of boys' cases. Six additional conduct and personality difficulties among girls yielded substantial correlations in the .30's but low coefficients below .20 among

boys: oversuggestibility, bad companions, loitering or wandering, truancy from school, lying, and bashfulness.

Mental conflict showed moderate correlations in the .20's with sex delinquency (coitus) among both sexes. Daydreaming and sulkiness among boys showed moderate correlations in the .20's but negligible coefficients of negative sign among girls. Seven miscellaneous notations among girls showed moderate correlations in the .20's but low coefficients below .20 among boys: immoral home conditions, incurability, disobedience, swearing or bad language (undifferentiated), stealing, lues, and underweight condition.

Sex delinquency (coitus) showed many negative correlations of moderate size in the -.20's: among boys for the four notations, laziness, lack of initiative, irregular attendance at school, and stuttering and among girls for the five notations, "nervousness," irritable temperament, restlessness in sleep, question or diagnosis of encephalitis, and neurological defect (unspecified). "Request for vocational guidance" yielded the substantial negative correlations of  $-.39 \pm .05$  and  $-.41 \pm .04$  among boys and girls respectively.

Sex delinquency (coitus) yielded substantial or large correlations ranging from .38 to .48 with four other sex notations—masturbation and overinterest in sex matters—among both sexes and the two notations for which only the girls' coefficients were calculated, overinterest in the opposite sex and victim of sex abuse by older child or person.

Among the seven physical or psychophysical disabilities, two showed moderate positive correlations in the .20's among girls, lues and underweight condition. Two showed moderate negative correlations in the -.20's among girls, question or diagnosis of encephalitis and neurological defect (unspecified). Stuttering among boys showed the doubtfully significant negative correlation of  $-.20 \pm .08$ , the girls' coefficient being omitted because of paucity of girls' cases.

Among the four home or familial notations the only statistically significant correlation with sex delinquency (coitus) was the moderate positive one of  $.29 \pm .03$  with immoral home conditions among girls.

Masturbation in our data was one of the most frequently appearing behavior notations, especially among boys. It was noted among 599, or 28.3 per cent, of our 2,113 White boys, and among 154, or 13.0 per cent, of our 1,181 White girls. With the personality-total and conduct-total criteria of seriousness or "ominousness" its bi-serial correlations ranging from .30 to .41 may be considered substantial but not large (Table 97). With the police-arrest criterion of overt juvenile delinquency its tetrachoric correlations of  $.20 \pm .03$  and  $.21 \pm .05$  were only moderate.

Its largest correlations were with overinterest in sex matters, the respective coefficients for boys and girls being  $.54 \pm .03$  and  $.46 \pm .04$ . Sex delinquency (coitus) yielded large correlations in the .40's among both sexes. Stealing among girls yielded a large correlation of  $.44 \pm .04$ , and a substantial coefficient of  $.32 \pm .02$  among boys.

Lying yielded substantial correlations in the .30's among both sexes. Daydreaming among boys yielded the substantial correlations of  $.37 \pm .03$ , but a moderate correlation among girls of  $.25 \pm .05$ . Among girls three notations—truancy from home, leading others into bad conduct, and worry over some specific fact—yielded substantial correlations in the .30's and among boys moderate coefficients ranging from .19 to .28.

Eleven personality and conduct problems showed moderate coefficients in the .20's with masturbation among both sexes: sensitiveness or worrisomeness (undifferentiated), sensitiveness over some specific fact, mental conflict, changeable moods or attitudes, "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated), nail-biting, inattentiveness in school, bad companions, destructiveness, swearing or bad language (undifferentiated), and exclusion from school. Two conduct problems for which only the boys' coefficients were calculated—swearing in general and teasing other children—and two notations for which only the girls' coefficients were calculated—overinterest in the opposite sex and victim of sex abuse by older child or person—also showed moderate correlations in the .20's. Six notations among boys showed moderate correlations in the .20's but low coefficients below .20 among girls: enuresis, inferiority feelings, boastful or "show-off" manner, fantastical lying, object of teasing by other children, and laziness. A large list of eighteen

## Other Correlations (Positive to Negative)

"Nervous," .19 and .19; Repressed, .19 and .04; Complaining of bad treatment by other children, .19 (boys); Smoking, .17 (boys); Hatred or jealousy of sibling, .17 and .15; Question of change of personality, .17 and .17; Unpopular, .17 and .18; Loitering, .16 and .00; Oversuggestible, .16 and .11; Conduct prognosis bad, .16 and .17; Spoiled child, .15 and .01; Neurological defect, .15 and .16; Staying out late at night, .11 and .11; Threatening violence, .14 (boys); Emotional instability, .14 and .16; Grouped: temper, etc., .14 and .11; Truancy from school, .13 and .19; Crying spells, .13 and .15; Popular, .13 and .01; Discord between parents, .13 and .11; Grouped: egocentric, etc., .13 and .18; Contrary, .12 and .10; Disturbing influence in school, .12 and .12; Irresponsible, .12 and .05; Gang, .12 (boys); Absent-minded, .12 and .15; Clean, .12 and .08; Attractive manner, .12 and .05; Inefficient in work, play, etc., .11 and .08; Quarrelsome, .11 and .18; Listless, .11 and .00; Irritable, .11 and -.01; Distractible, .11 and .14; Excuse-forming, .10 and .11; Irregular sleep habits, .10 and .03; Selfish, .09 and .18; Apprehensive, .09 and .10; Egocentric, .09 and .14; Vicious home conditions, .09 and .07; Sulky, .08 and .18; Bashful, .08 and -.07; Sensitive (general), .08 and .06; Finicky food habits, .07 and .13; Preference for younger children, .07 and .16; Headaches, .07 and .14; Lack of interest in school, .06 and .10; Refusal to attend school, .06 and .02; Temper display, .06 and -.07; Leader, .06 and .15; Seclusive, .05 and .12; Underweight, .04 and .00; Speech defect, .04 and .08; Immoral home conditions, .04 and .11; Former convulsions, .02 and -.04; Poor work in school, .01 and -.09; Follower, .01 and -.09; Lack of initiative, .00 and -.13; Irregular attendance at school, -.01 and -.03; Grouped: dull, slow, etc., -.01 and -.12; Brother in penal detention, -.02 and -.01; Question of hypochondria, -.03 and .00; Slow, dull, -.04 and -.05; Lues, -.04 and .06; Stuttering, -.06 (boys); Feeble-minded sibling, -.08 and -.10; Retardation in school, -.14 and -.15

Omitted—Sex denied entirely

miscellaneous case-record notations among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: incorrigibility, disobedience, defiant attitude, stubbornness, fighting, violence, temper tantrums, rudeness, bossy manner, sullenness, slovenliness, restlessness, restlessness in sleep, queer behavior, psychoneurotic trends, depressed mood or spells, unhappiness, and question or diagnosis of encephalitis.

The only negative correlation of significant size was with the routine item "request for vocational guidance,"  $-.37 \pm .04$  among girls.

Among the six sex notations the intercorrelations of masturbation with the two sex traits sex delinquency (coitus) and overinterest in sex matters were large, as we have noted, ranging from .41 to .54 among both sexes. With two notations for which only the girls' correlations were computed—overinterest in the opposite sex and victim of sex abuse by older child or person—the coefficients were of moderate size in the .20's.

Among the seven physical or psychophysical disabilities moderate correlations in the .20's were found for enuresis among boys and question or diagnosis of encephalitis among girls.

With the four home or familial notations all correlations with masturbation were low or negligible, ranging from  $-.02$  to  $.13$ .

Manifesting precocious interest or overinterest in the opposite sex was noted among 175 of our 1,181 White girls (14.8 per cent). Its incidence among our boys was so small that satisfactory correlation coefficients could not be computed. Its bi-serial correlation with conduct-total was fairly large,  $.47 \pm .03$ , and with the personality-total probably substantial,  $.31 \pm .03$  (Table 98). Its correlation with police arrest was low,  $.18 \pm .04$ .

Its largest correlation,  $.50 \pm .04$ , was with staying out late at night. Five conduct problems also yielded large correlations in the .40's: bad companions, truancy from school, incorrigibility, lying, and staff notation of unfavorable conduct prognosis.

Overinterest in the opposite sex yielded substantial correlations in the .30's with the following seventeen conduct and personality notations: sex delinquency (coitus), overinterest in sex matters, leading others into bad conduct, truancy from home,

## Other Correlations (Positive to Negative)

Disturbing influence in school, .19; Psychoneurotic, .19; Distractible, .19; Grouped: depressed, etc., .18; Grouped: fighting, etc., .18; Oversuggestible, .18; Depressed, .17; Restless, .17; Poor work in school, .17; Inattentive in school, .16; Lazy, .15; Grouped: "nervous," etc., .15; Daydreaming, .14; Nail-biting, .14; Quarrelsome, .14; Headaches, .13; Listless, .11; Irritable, .11; Leader, .11; Question of encephalitis, .10; Mental conflict, .10; Absent-minded, .09; Object of teasing, .09; Worry over specific fact, .09; Immoral home conditions, .08; Hatred or jealousy of sibling, .08; Finicky food habits, .07; Discord between parents, .07; Grouped: sensitive or worrisome, etc., .06; Sulky, .06; Boasy, .06; Irregular sleep habits, .05; Sensitive over specific fact, .05; Vicious home conditions, .05; Brother in penal detention, .04; Neurological defect, .04; Enuresis, .04; Crying spells, .03; Feeble-minded sibling, .02; Irregular attendance at school, .02; Spoiled child, .02; Repressed, .02; Restless in sleep, .02; Selfish, .02; Preference for younger children, .01; Former convulsions, -.00; Apprehensive, -.00; Underweight, -.01; "Nervous," -.01; Temper display, -.01; Question of hypomania, -.03; Popular, -.03; Attractive manner, -.03; Sex denied entirely, -.04; Apprehensive, -.05; Follower, -.05; Sensitive (general), -.06; Clean, -.07; Grouped: dull, slow, etc., -.07; Bashful, -.09; Slow, dull, -.11; Inferiority feelings, -.11; Vocational guidance, -.11; Seclusive, -.13; Speech defect, -.15

loitering or wandering, disobedience, violence, temper tantrums, destructiveness, stealing, rudeness, boastful or "show-off" manner, fantastical lying, swearing or bad language (undifferentiated), queer behavior, unpopularity, and exclusion from school.

Moderate correlations in the .20's were found for nineteen notations: masturbation, victim of sex abuse by older child or person, stubbornness, defiant attitude, contrariness, sullenness, refusal to attend school, lack of interest in school, inefficiency in work, play, etc., slovenliness, irresponsibility, egocentricity, fighting, excuse-forming attitude, emotional instability, changeable moods or attitudes, question of change of personality, unhappiness, and lues.

Only one negative correlation of significant size was found—lack of initiative—with a coefficient of  $-.23 \pm .06$ .

Among its intercorrelations with five other sex notations, overinterest in the opposite sex yielded substantial correlations in the .30's with sex delinquency (coitus) and overinterest in sex matters, and moderate coefficients in the .20's with masturbation and victim of sex attack or abuse by older child or person.

Among the six physical or psychophysical disabilities considered in Table 98, the only correlation of moderate size was with lues,  $.21 \pm .05$ .

Among the four home or familial notations all correlations were negligible, ranging from .04 to .08.

Manifesting precocious interest or overinterest in sex matters was noted among 86 of our 2,113 White boys, or 4.1 per cent, and among 81 of our 1,181 White girls, or 6.9 per cent. With personality-total and conduct-total its bi-serial correlations were substantial, ranging from .31 to .42 (Table 99). With police arrest its tetrachoric correlations were of moderate size in the

.20's. Its highest correlations, ranging from .46 to .54 among both sexes, were with masturbation and sex delinquency (coitus). Victim of sex abuse by older child or person (calculated only for girls) also yielded a large correlation of .44 ± .05. Four undesirable behavior traits among girls similarly yielded large correlations in the .40's but moderate coefficients in the .20's among boys: mental conflict, worry over some specific fact, leading others into bad conduct, and lying.

Overinterest in sex matters yielded substantial correlations in the .30's among both sexes with swearing or bad language (undifferentiated) and among girls with overinterest in the opposite sex, the boys' coefficient not being calculated because of paucity of cases. Immoral home conditions and staff notation of unfavorable conduct prognosis among boys yielded substantial correlations in the .30's but low coefficients of .17 and .15 respectively among girls. Three conduct problems yielded substantial correlations in the .30's among girls, and moderate coefficients in the .20's among boys: bad companions, boastful or "show-off" manner, and fantastical lying. An additional eight miscellaneous notations among girls yielded substantial correlations in the .30's but low coefficients below .20 among boys: disobedience, violence,

egocentricity, bossy manner, rudeness, hatred or jealousy of sibling, inattentiveness in school, and headaches.

Overinterest in sex matters among both sexes showed moderate correlations in the .20's with four undesirable notations: sensitiveness or worrisomeness (undifferentiated), sensitiveness over some specific fact, excuse-forming attitude, and exclusion from school. Among boys psychoneurotic trends and preference for younger children as playmates showed moderate correlations in the .20's but low coefficients below .20 among girls. Ten behavior traits among girls showed moderate correlations in the .20's but low coefficients below .20 among boys: daydreaming, distractibility, inferiority feelings, unhappiness, queer behavior, sullenness, slovenliness, disturbing influence in school, stealing, and "leader."

There were four negative correlations of moderate size in the -.20's with overinterest in sex matters, all among girls: question of hypophrenia, dull or slow manner (including listlessness and lack of initiative, undifferentiated), former convulsions, and feeble-minded sibling.

Among the five intercorrelations of overinterest in sex matters with the other sex notations, consistently large coefficients ranging from .44 to .54 were found for the three traits, sex delinquency (coitus), masturbation, and (calculated for girls only) victim of sex abuse by older child or person. A fairly substantial correlation of .30 + .05 was found for overinterest in the opposite sex, for which only the girls' correlations were calculated.

Among the seven physical or psychophysical disabilities all correlations were low or negligible, ranging from -.14 to .14.

Among the four home or familial notations the only correlation of significant size with overinterest in sex matters was .30 + .07 with immoral home conditions among boys.

The case-record notation, victim of actual or attempted rape or sex abuse by adult person (not a relative) or by older child, was noted among 104 of our 1,181 White girls, or 8.8 per cent. Among boys it occurred so seldom that correlations were not feasible in our data. As an indicator of behavior disorder it appears to be of little meaning. With the conduct-total its correlation was only moderate, .21 + .03, while with the personality-total and police arrest its correlations were low, .11 + .03 and

.19 ± .05 (Table 100). Its largest correlations, .44 ± .04 and .44 ± .05, were with sex delinquency (coitus) and overinterest in sex matters respectively. Substantial correlations in the .30's

were yielded by vicious home conditions and inattentiveness in school.

Victim of sex abuse by older child or person showed moderate correlations in the .20's with the following eleven miscellaneous notations: overinterest in the opposite sex, masturbation, bad companions, truancy from home, lying, swearing or bad language (undifferentiated), apprehensiveness, unhappiness, mental conflict, discord between parents, and staff notation of unfavorable conduct prognosis.

Negative correlations of moderate size in the -.20's were found for the following four notations: sex misbehavior denied entirely, irritable temperament, temper display, and destructiveness.

Among the five intercorrelations between victim of sex abuse by older child or person and the other sex notations, large correlations in the .40's were found for sex delinquency (coitus) and overinterest in sex matters and moderate coefficients in the .20's with masturbation and overinterest in the opposite sex. With sex misbehavior denied entirely the correlation was negative and of moderate size,  $-.28 \pm .07$ .

With the six physical or psychophysical disabilities con-

sidered in Table 100, all coefficients were low or negligible, ranging from  $-.11$  to  $.11$ .

Among the four home or familial notations, vicious home conditions yielded the substantial correlation of  $.33 \pm .06$ , discord between parents the moderate correlation of  $.20 \pm .05$ , and immoral home conditions and brother in penal detention the low positive coefficients of  $.18$  and  $.17$  respectively with victim of sex abuse by older child or person.

The notation sex misbehavior denied entirely (i.e., patient denies masturbation, sex delinquency, homosexual practices, etc.) was employed when there was no information contradicting the child's own denials. It was noted among 142 boys, or 6.7 per cent, and among 47 girls, or 4.0 per cent. The data in this instance are of course very incomplete, because in the clinical examinations it was not always considered advisable to investigate exhaustively the child's sex misbehavior beyond what was objectively verifiable. Its correlations with our three criteria of seriousness were all low or negligible, ranging from  $-.16$  to  $.17$  (Table 101).

Bad companions, .19 and -.14; Follower, .16 and -.08; Immoral home conditions, .16 and .16; Slovenly, .15 and .10; Staying out late at night, .15 and .02; Enuresis, .13 and .12; Mental conflict, .13 and -.11; Leading others into bad conduct, .12 and -.13; Rude, .12 and -.01; Spoiled child, .12 and .17; Lack of interest in school, .11 and .04; Leader, .11 and .12; Stealing, .10 and .10; Sullen, .10 and .07; Apprehensive, .10 and -.10; Brother in penal detention, .10 and .06; Discord between parents, .10 and .16; Seclusive, .09 and .14; Unhappy, .09 and .11; Headaches, .09 and .04; Lues, .09 and .04; Speech defect, .09 and -.15; Contrary, .08 and .09; Incorrigible, .08 and -.06; Loitering, .08 and -.18; Nail-biting, .08 and .13; Sulky, .08 and -.07; Psychoneurotic, .08 and -.05; Disobedient, .07 and -.05; Disturbing influence in school, .07 and .03; Sensitive over specific fact, .07 and .11; Repressed, .07 and .12; Poor work in school, .07 and .01; Irregular attendance at school, .07 and .11; Teasing other children, .06 (boys); Refusal to attend school, .06 and .19; Slow, dull, .06 and -.19; Queer, .06 and .10; Complaining of bad treatment by other children, .06 (boys); Grouped: dull, slow, etc., .06 and -.07; Grouped: sensitive or worrisome, etc., .06 and .06; Sensitive (general), .05 and .18; Fighting, .04 and .09; Popular, .04 and .13; Boastful, "show-off," .04 and .18; Question of change of personality, .03 and .17; Unpopular, .03 and .08; Neurological defect, .03 and .11; Grouped: lack of interest in school, etc., .03 and -.04; Lying, .02 and .07; Quarrelsome, .02 and .16; Excuse-forming, .02 and .00; Object of teasing, .02 and -.13; Oversuggestible, .02 and -.04; Restless in sleep, .02 and .05; Stubborn; .01 and .11; Restless, .01 and .09; Grouped: depressed, etc., .01 and .18; Defiant, .00 and .07; Vocation guidance, .00 and .01; Absent-minded, .00 and -.18; Feeble-minded sibling, -.00 and -.01; Grouped: egocentric, etc., -.00 and .02; Smoking, -.01 (boys); Former convulsions, -.01 and -.12; Egocentric, -.02 and .05; Distractible, -.02 and .07; "Nervous," -.02 and .14; Grouped: disobedient, etc., -.03 and -.05; Inefficient in work, play, etc., -.04 and .13; Worry over specific fact, -.04 and -.09; Inferiority feelings, -.04 and .05; Question of encephalitis, -.04 and .17; Overinterest in opposite sex, -.04 (girls); Destructive, -.05 and -.02; Temper display, -.05 and -.14; Listless, -.05 and .15; Grouped: swearing, etc., -.05 and .03; Selfish, -.06 and .08; Preference for younger children, -.06 and .06; Threatening violence, -.07 (boys); Violence, -.07 and .09; Stuttering, -.07 (boys); Grouped: fighting, etc., -.07 and .09; Finicky food habits, -.08 and .10; Temper tantrums,

TABLE 101—Continued

-.08 and .13; Grouped: "nervous," etc., -.08 and .14; Retardation in school, -.09 and .03; Swearing (general), -.10 (boys); Irresponsible, -.11 and .02; Question of hypophrenia, -.11 and -.01; Exclusion from school, -.11 and -.08; Bossy, -.12 and .10; Bashful, -.13 and -.07; Daydreaming, -.16 and .13; Grouped: temper, etc., -.16 and .04; Irritable, -.17 and .08; Emotional instability, -.18 and -.03; Fantastical lying, -.19 and -.00

Omitted—Sex delinquency (coitus), Masturbation

Its highest correlations were only of moderate size in the .20's. Among boys five behavior traits showed correlations ranging from .20 to .25: attractive manner, truancy from school, hated or jealousy of sibling, crying spells, and (calculated for boys only) running with a gang. The corresponding girls' coefficients were low, ranging from .01 to .15. Among girls five notations showed moderate correlations in the .20's but low coefficients among boys ranging from -.13 to .13: clean habits, depressed mood or spells, changeable moods or attitudes, irregular sleep habits, and underweight condition.

Sex misbehavior denied entirely among girls showed four negative correlations of moderate size in the -.20's: truancy from home, inattentiveness in school, vicious home conditions, and (computed for girls only) victim of sex abuse by older child or person.

Among the three sex notations for which tetrachoric correlations with sex misbehavior denied entirely were calculated, the only one of significant size was the moderate negative coefficient of  $-.28 \pm .07$  with victim of sex abuse by older child or person (computed for girls only).

Among the seven physical or psychophysical disabilities the only coefficient of probable significant size was the moderate one of  $.21 \pm .06$  with underweight condition among girls.

Among the four home or familial notations all correlations with sex misbehavior denied entirely were low or negligible with the exception of the very doubtfully significant negative coefficient of  $-.20 \pm .09$  with vicious home conditions among girls.

A few words summarizing the trends in the six tables discussed in this chapter may be appropriate in view of the considerable prominence given to sex behavior in children's behavior clinics. Among both boys and girls, sex problems appear to be

conspicuously intercorrelated with one another. Among girls, sex notations are frequently associated to a considerable extent with conduct and personality disorders of nonsexual character, but among boys such correlations appear to be of relatively minor degree. Among girls the highest correlation was between sex delinquency (coitus) and the fact of police arrest or detention,  $.76 \pm .02$ . With physical defects the correlations were largely low or negligible. With immoral home conditions and vicious home conditions there were occasionally correlations of moderate or substantial size. With discord between parents there appeared to be almost no relationship with sex notations.

## CHAPTER LI

### ENURESIS; NAIL-BITING; AND FINICKY FOOD HABITS

The three "nervous habits"—enuresis, nail-biting, and finicky food habits—showed only minor correlations either among themselves or with the other notations considered in this study. So far as our correlational results indicate, all three appear to be of little importance clinically, with the possible exception of the correlation of finicky food habits with the personality-total among girls with the fairly high bi-serial coefficient of  $.41 \pm .03$ .

Enuresis or bed-wetting (present or former) was considered a conduct problem in our present study if it continued beyond the third birthday into the third year of age. (The appropriateness of our including enuresis in our conduct-total is admittedly open to question, and the writer in retrospect now feels that it should not have been so included. The effect upon our correlational results, however, is probably of little importance.) It was noted as having occurred among 576, or 27.3 per cent, of our 2,113 White boys and among 250, or 21.2 per cent, of our 1,181 White girls and is thus a frequently noted item, though only seldom did it appear to be a principal reason for referring the child to the clinic for examination. Its bi-serial correlations with the personality-total and conduct-total were low, ranging from .16 to .20 (Table 102). With police arrest its tetrachoric correlations for boys and girls respectively were  $.07 \pm .03$  and  $-.25 \pm .04$ . Its largest correlations with specific behavior problems were only .32 among girls and .26 among boys.

Its highest correlation,  $.32 \pm .03$ , was found among girls for the "broader grouping" of "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated), the corresponding coefficient among boys being low, .11. Restlessness in sleep showed the moderate correlations of  $.26 \pm .03$  and  $.31 \pm .04$  among boys and girls respectively. Mental conflict

## Other Correlations (Positive to Negative)

Destructive, .19 and .09; Grouped: sensitive or worrisome, etc., .19 and .13; Stealing, .18 and .19; Teasing other children, .17 (boys); Sulky, .16 and .09; Exclusion from school, .16 and .17; Former convulsions, .16 and .13; Slovenly, .15 and .13; Temper display, .15 and .10; Truancy from school, .15 and .12; Inferiority feelings, .15 and .10; Leading others into bad conduct, .14 and .10; Crying spells, .14 and .17; Fighting, .13 and .19; Lying, .13 and .19; Truancy from home, .13 and -.00; Conduct prognosis bad, .13 and .00; Spoiled child, .13 and .10; Sex denied entirely, .13 and .12; Boastful, "show-off," .12 and .08; Oversuggestible, .12 and -.03; Discord between parents, .12 and -.00; Finicky food habits, .11 and .19; Disobedient, .11 and .12; Fantastical lying, .11 and .15; Incorrigible, .11 and .17; Smoking, .11 (boys); Changeable mood, .11 and .01; Listless, .11 and .18; "Nervous," .11 and .19; Vicious

TABLE 102—Continued

home conditions, .11 and .01; Victim of sex abuse, .11 (girls); Bad companions, .10 and .00; Bossy, .10 and .17; Contrary, .10 and -.03; Excuse-forming, .10 and .13; Headaches, .10 and .09; Threatening violence, .09 (boys); Rude, .09 and .07; Distractible, .09 and .18; Sensitive (general), .09 and .14; Worry over specific fact, .09 and .09; Follower, .09 and .06; Lack of initiative, .08 and .05; Object of teasing, .08 and .14; Staying out late at night, .07 and .15; Psychoneurotic, .07 and -.07; Repressed, .07 and .12; Grouped: dull, slow, etc., .07 and .04; Apprehensive, .06 and .07; Underweight, .06 and .11; Grouped: depressed, etc., .06 and .13; Inattentive in school, .05 and .09; Lack of interest in school, .05 and .04; Bashful, .05 and .02; Queer, .05 and .08; Question of hypophrenia, .05 and .16; Inefficient in work, play, etc., .04 and .19; Absent-minded, .04 and .14; Egocentric, .04 and .08; Unhappy, .04 and -.01; Grouped: lack of interest in school, etc., .04 and .09; Overinterest in opposite sex, .04 (girls); Defiant, .03 and .16; Loitering, .03 and .12; Hatred or jealousy of sibling, .03 and .09; Depressed, .03 and .18; Slow, dull, .03 and .05; Irregular sleep habits, .03 and .11; Seclusive, .03 and .05; Complaining of bad treatment by other children, .03 (boys); Neurological defect, .03 and .06; Grouped: egocentric, etc., .03 and .05; Emotional instability, .02 and .08; Popular, .02 and -.03; Lues, .02 and .15; Overinterest in sex matters, .02 and .14; Irregular attendance at school, .02 and .01; Brother in penal detention, .02 and -.11; Retardation in school, -.00 and .04; Sullen, -.00 and -.07; Immoral home conditions, -.01 and .03; Attractive manner, -.01 and -.02; Clean, -.01 and .12; Poor work in school, -.01 and -.13; Sex delinquency (coitus), -.01 and .05; Gang, -.02 (boys); Irresponsible, -.02 and .07; Stuttering, -.03 (boys); Question of change of personality, -.04 and .07; Leader, -.06 and .18; Selfish, -.06 and .12; Refusal to attend school, -.07 and .12; Vocational guidance, -.10 and -.18; Feeble-minded sibling, -.17 and .01

and temper tantrums or display (including irritable temperament, undifferentiated) also yielded moderate or possibly substantial coefficients of .31 each among the girls, and low coefficients of .03 and .16 respectively among boys.

Enuresis showed moderate correlations in the .20's among both sexes with temper tantrums and also with swearing in general, for which only the boys' coefficients were computed. Sensitive-ness over some specific fact and masturbation among boys showed moderate correlations in the .20's but low positive coefficients below .20 among girls. Fourteen miscellaneous notations among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: nail-biting, restlessness, irritable temperament, quarrelsomeness, violence, stubbornness, swearing or bad language (undifferentiated), disturbing influence in school, laziness, preference for younger children as playmates, daydreaming, unpopularity, speech defect (other than stuttering), and question or diagnosis of encephalitis.

The only negative correlation of moderate size was the interesting one with police arrest among girls,  $-.25 \pm .04$ .

Among the six sex notations the only correlations of meaningful size were with masturbation, the respective coefficients for boys and girls being  $.24 \pm .03$  and  $.19$ .

Among the six physical or psychophysical disabilities, for which correlations with enuresis were calculated, there were two of moderate size, both among girls: question or diagnosis of encephalitis,  $.22 \pm .07$ , and speech defect (other than stuttering),  $.22 \pm .05$ .

Among the four home or familial notations, all correlations were low or negligible, ranging from  $-.11$  to  $.12$ .

Enuresis in our data, therefore, appears to have little meaning other than as an annoyance in itself.

Nail-biting was noted among 300 of our boys, or in 14.2 per cent, and among 246 of our girls, or in 20.8 per cent. Its incidence thus appears to be definitely greater among girls. With the personality-total its bi-serial correlations among both sexes were of moderate size in the .20's. With the conduct-total its correlations were low,  $.19 \pm .02$  and  $.17 \pm .03$  for boys and girls respectively. With police arrest its corresponding tetrachoric correlations of  $.10 \pm .03$  and  $.06 \pm .04$  respectively were negligible (Table 103).

Other Correlations (Positive to Negative)

Lying, .19 and .18; Grouped: depressed, etc., .19 and .15; Inferiority feelings, .18 and .13; Defiant, .18 and .15; Swearing (general), .18 (boys); Contrary, .17 and -.09; Rude, .17 and .12; Truancy from school, .17 and .17; Daydreaming, .17 and .08; Grouped: temper, etc., .17 and .19; Teasing other children, .16 (boys); Selfish, .16 and .17; Smoking, .16 (boys); Depressed, .16 and .17; Grouped: egocentric, etc., .16 and .10; Exclusion from school, .15 and .18; Grouped: swearing, etc., .15 and .16; Truancy from home, .14 and .16; Queer, .14 and .18; Overinterest in opposite sex, .14 (girls); Headaches, .14 and .18; Loitering, .13 and .06; Temper tantrums, .13 and .13; Threatening violence, .13 (boys); Complaining of bad treatment by other children, .13 (boys); Grouped: disobedient, etc., .13 and .11; Grouped: sensitive, etc., .13 and .19; Temper display, .12 and .11; Question of change of personality, .12 and .13; Egocentric, .12 and .04; Irritable, .12 and .16; Spoiled child, .12 and .13; Bad companions, .11 and .04; Inattentive in school, .11 and .11; Incurrigible, .11 and .18; Worry over specific fact, .11 and .16; Former convulsions, .11 and .05; Boastful, "show-off," .10 and .17; Lazy, .10 and .01; Stubborn, .10 and .09; Psychoneurotic, .10 and -.01; Sensitive over specific fact, .10 and .17; Follower, .10 and .13; Disobedient, .09 and .07; Inefficient in work, play, etc., .09 and -.02; Apprehensive, .09 and .15; Excuse-forming, .09 and .04; Seclusive, .09 and -.04; Sensitive (general), .09 and .11; Attractive manner, .09 and .06; Irregular attendance at school, .09 and .03; Discord between parents, .09 and .12; Lack of interest in school, .08 and .08; Quarrelsome, .08 and .16; Absent-minded, .08 and .08; Distractible, .08 and .19; Sex denied entirely, .08 and .13; Question of encephalitis, .08 and .13; Sex delinquency (ocitus), .07 and .03; Object of teasing, .07 and .19; Vicious home conditions, .07 and -.01; Staying out late at night, .06 and .07; Conduct prognosis bad, .06 and .06; Leader, .06 and .06; Vocational guidance, .06 and -.05; Victim of sex abuse, .06 (girls); Refusal to attend school, .05 and -.06; Sullen, .05 and .09; Mental conflict, .05 and .06; Speech defect, .05 and .18; Leading others into bad conduct, .04 and .08; Sulky, .04 and .02; Bashful, .04 and .01; List-

TABLE 103—Continued

less, .04 and -.17; Repressed, .04 and .06; Popular, .04 and -.07; Grouped: lack of interest in school, etc., .04 and .08; Gang, .03 (boys); Oversuggestible, .03 and .05; Lack of initiative, .02 and .03; Overinterest in sex matters, .01 and .09; Stuttering, .01 (boys); Lues, .00 and .04; Clean, -.01 and .04; Underweight, -.02 and .07; Poor work in school, -.02 and -.10; Feeble-minded sibling, -.03 and -.15; Question of hypophrenia, -.03 and .06; Retardation in school, -.04 and -.05; Grouped: dull, slow, etc., -.05 and -.07; Emotional instability, -.06 and .13; Slow, dull, -.07 and -.08; Immoral home conditions, -.12 and .12; Brother in penal detention, -.14 and -.11

Its largest correlations of  $.40 \pm .04$  and  $.37 \pm .03$  were found among girls for restlessness in sleep and "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated) respectively, the corresponding coefficients among boys being of moderate size in the .20's.

Nail-biting showed moderate correlations in the .20's with sex personality and conduct problems: "nervousness," restlessness, changeable moods or attitudes, crying spells, bossy manner, and masturbation. The three behavior notations slovenliness, unhappiness, and fantastical lying among boys showed moderate correlations ranging from .21 to .31 but low coefficients below .20 among girls. Thirteen miscellaneous notations among girls showed moderate coefficients ranging from .20 to .30 but low coefficients below .20 among boys: enuresis, finicky food habits, fighting, violence, hatred or jealousy of sibling, destructiveness, disturbing influence in school, irregular sleep habits, stealing, irresponsibility, unpopularity, preference for younger children as playmates, and neurological defect (unspecified).

Among the six sex notations, nail-biting showed moderate correlations in the .20's with masturbation among both sexes.

Among the seven physical or psychophysical disabilities, enuresis and neurological defect (unspecified) showed moderate correlations in the .20's among girls.

Among the four home or familial notations all correlations were low or negligible.

"Finicky" food habits or capricious or irregular appetite was noted among 236 boys, or 11.2 per cent, and among 105 girls, or 8.9 per cent. Among girls it appeared to be of some significance as an indicator of personality deviation, its correlation

with personality-total being  $.41 \pm .03$  (Table 104). Among girls its correlations with conduct-total and police arrest were of moderate size in the .20's. Among boys it showed a moderate correlation of  $.26 \pm .02$  with personality-total, but low or negligible correlations with conduct-total and police arrest.

## Other Correlations (Positive to Negative)

Boastful, "show-off," .17 and .18; Destructive, .17 and .12; Underweight, .16 and .18; Bossy, .15 and .03; Follower, .14 and .12; Grouped: depressed, etc., .14 and .13; Sulky, .13 and .15; Swearing (general), .13 (boys); Depressed, .13 and .17; Queer, .13 and .04; Listless, .12 and .10; Emuresis, .11 and .19; Overinterest in sex matters, .11 and -.06; Sensitive over specific fact, .11 and .05; Clean, .11 and .18; Teasing other children, .10 (boys); Distractable, .10 and .13; Emotional instability, .10 and .06; Unhappy, .10 and .12; Disturbing influence in school, .09 and .08; Apprehensive, .09 and .11; Attractive manner, .09 and .14; Bad companions, .08 and .11; Lazy, .08 and .06; Threatening violence, .08 (boys); Absent-minded, .08 and -.04; Lack of initiative, .08 and .11; Smoking, .07 (boys); Staying out late at night, .07 and .13; Masturbation, .07 and .13; Bashful, .07 and .14; Repressed, .07 and .15; Overinterest in opposite sex, .07 (girls); Inefficient in work, play, etc., .05 and -.06; Lying, .05 and .12; Object of teasing, .05 and .14; Preference for younger children, .05 and .04; Stuttering, .05 (boys); Grouped: lack of interest in school, etc., .05 and .18; Poor work in school, .04 and -.02; Vicious home conditions, .04 and -.17; Truancy from home, .03 and .02; Hatred or jealousy of sibling, .03 and .02; Complaining of bad treatment by other children, .03 (boys); Unpopular, .02 and .11; Mental conflict, .02 and -.07; Grouped: dull, slow, etc., .02 and -.02; Excuse-forming, .02 and .14; Fantastical lying, .01 and .19; Slovenly, .01 and .03; Truancy from school, .00 and .11; Exclusion from school, .00 and .14; Speech defect, -.00 and -.11; Leader, -.00 and .17; Vocational guidance, -.01 and .02; Lack of interest in school, -.01 and .09; Irresponsible, -.01 and .06; Lues, -.02 and .05; Gang, -.02 (boys); Loitering, -.02 and .15; Sex delinquency (coitus), -.03 and -.04; Leading others into bad conduct, -.03 and .19; Oversuggestible, -.04 and .12; Stealing, -.04 and .06; Feeble-minded sibling, -.06 and -.13; Question of hypophrenia, -.06 and -.15; Sex denied entirely, -.08 and .10; Brother in penal detention, -.09 and .06; Slow, dull, -.09 and -.12; Victim of sex abuse, -.11 (girls); Immoral home conditions, -.14 and -.16; Retardation in school, -.15 and -.11

Among girls its largest correlations ranging from .42 to .45 were with "nervousness" or restlessness (including irritable

temperament and changeable moods, undifferentiated), temper tantrums or display (including irritable temperament, undifferentiated), and irritable temperament, the corresponding coefficients for boys being of moderate size ranging from .22 to .31. Selfishness among girls similarly yielded the fairly large correlation of  $.40 \pm .06$  but a low coefficient of .13 among boys.

Three notations—restlessness in sleep, irregular sleep habits, and sensitiveness in general—yielded substantial correlations in the .30's among both sexes. Six notations among girls yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: nail-biting, violence, defiant attitude, refusal to attend school, question or diagnosis of encephalitis, and former convulsions.

Finicky food habits showed moderate correlations in the .20's among both sexes for the three notations, "spoiled child," restlessness, and headaches. Four traits among boys showed moderate correlations in the .20's but low coefficients below .20 among girls: question of change of personality, changeable moods or attitudes, sensitiveness or worrisomeness (undifferentiated), and popularity. A large list of twenty-two miscellaneous case-record notations among girls showed moderate correlations in the .20's but low or negligible coefficients below .20 among boys: incorrigibility, disobedience, contrariness, stubbornness, fighting, quarrelsomeness, temper display, rudeness, egocentricity, sullenness, swearing or bad language (undifferentiated), inattentiveness in school, daydreaming, seclusiveness, inferiority feelings, worry over some specific fact, psychoneurotic trends, crying spells, irregular attendance at school, discord between parents, neurological defect (unspecified), and staff notation of unfavorable conduct prognosis.

Among the six sex notations all correlations with finicky food habits were low or negligible, ranging from -.11 to .11.

Among the seven physical or psychophysical disabilities there were two correlations of statistically significant size, both among girls: question or diagnosis of encephalitis,  $.35 \pm .08$ , and neurological defect (unspecified),  $.20 \pm .06$ .

Among the four home or familial notations, the only coefficient of moderate size was with discord between parents among girls,  $.21 \pm .05$ .

CHAPTER LII

BOASTFUL OR "SHOW-OFF" MANNER

From the standpoint of clinical importance, boastful or "show-off" manner appeared in our data to be of considerable importance, especially among girls. With both the personality-total and the conduct-total the bi-serial correlations among girls were in the .50's and the corresponding correlations among boys in the .40's (Table 105). With the police-arrest criterion of juvenile

## Other Correlations (Positive to Negative)

Restless in sleep, .19 and .13; Attractive manner, .19 and .09; Irresponsible, .18 and .16; Loitering, .18 and .16; Complaining of bad treatment by other children, .18 (boys); Finicky food habits, .17 and .18; Sullen, .17 and .14; Temper display, .17 and .08; "Nervous," .16 and .15; Object of teasing, .16 and .13; Popular, .16 and .18; Worry over specific fact, .15 and .11; Victim of sex abuse, .15 (girls); Swearing (general), .14 (boys); Grouped: sensitive or worrisome, etc., .14 and .19; Sensitive over specific fact, .13 and .11; Enuresis, .12 and .08; Absent-minded, .12 and .16; Poor work in school, .12 and .14; Discord between parents, .12 and .03; Oversuggestible, .11 and .15; Nail-biting, .10 and .17; Former convulsions, .10 and -.03; Refusal to attend school, .08 and .00; Question of change of personality, .08 and .14; Preference for younger children, .08 and -.06; Brother in penal detention, .08 and -.19; Seclusive, .06 and .08; Vicious home conditions, .06 and .03; Neurological defect, .05 and -.07; Sex denied entirely, .04 and .18; Crying spells, .03 and .17; Irregular attendance at school, .03 and .02; Sex delinquency (coitus), .02 and .09; Apprehensive, .02 and .18; Vocational guidance, .01 and .06; Immoral home conditions, .00 and -.03; Stuttering, -.02 (boys); Listless, -.03 and .14; Bashful, -.03 and .11; Speech defect, -.07 and -.05; Question of hypophrenia, -.08 and -.05; Grouped: dull, slow, etc., -.10 and -.01; Underweight, -.11 and -.01; Lues, -.15 and .10; Retardation in school, -.17 and -.08; Slow, dull, -.17 and -.03

delinquency its tetrachoric correlation of  $.29 \pm .03$  among boys was of moderate size, while the corresponding coefficient for girls was low,  $.10 \pm .06$ . It was noted among 251, or 11.9 per cent, of our 2,113 White boys and among 77, or 6.5 per cent, of our 1,181 White girls. It yielded high correlations in the .50's with fantastical lying and disturbing influence in school among boys and meaningful coefficients of  $.37 \pm .07$  and  $.44 \pm .06$  among girls. Quarrelsomeness among boys yielded the large correlation of  $.41 \pm .03$  and a moderate coefficient of  $.27 \pm .05$  among girls. Four undesirable behavior traits among girls yielded large correlations in the .40's and substantial coefficients in the .30's among boys: egocentricity, bossy manner, rudeness, and unpopularity. Violence

and temper tantrums among girls also yielded substantial correlations in the .40's but moderate correlations in the .20's among boys. Three personality difficulties among girls similarly yielded large correlations in the .40's but low coefficients below .20 among boys: changeable moods or attitudes, daydreaming, and queer behavior.

Boastful or "show-off" manner yielded substantial correlations in the .30's among both sexes with the four behavior problems, "spoiled child," disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated), lying, and leading others into bad conduct. The two conduct problems for which only the boys' coefficients were calculated—teasing other children and smoking—and also overinterest in the opposite sex, for which only the girls' coefficient was computed, also yielded substantial coefficients in the .30's. Three conduct problems yielded substantial correlations in the .30's among boys and moderate correlations in the .20's among girls: fighting, disobedience, and stealing. Seven conduct and personality problems among girls yielded substantial correlations in the .30's and moderate coefficients in the .20's among boys: defiant attitude, incorrigibility, swearing or bad language (undifferentiated), selfishness, restlessness, excuse-forming attitude, and overinterest in sex matters. Six notations among girls yielded substantial correlations in the .30's and low positive coefficients below .20 among boys: emotional instability, psychoneurotic trends, distractibility, inefficiency in work, play, etc., sensitiveness in general, and headaches.

Boastful or "show-off" manner showed moderate correlations in the .20's with eight behavior traits among both sexes: inferiority feelings, "leader," contrariness, laziness, sulkiness, truancy from school, irregular sleep habits, and hatred or jealousy of sibling. Two conduct problems for which only the boys' correlations were computed also showed moderate correlations in the .20's: threatening violence and running with a gang. Nine notations showed moderate correlations in the .20's among boys but low coefficients below .20 among girls: inattentiveness in school, lack of interest in school, exclusion from school, bad companions, staying out late at night, destructiveness, mental conflict, masturbation, and clean habits. Nine case-record notations among girls showed moderate correlations in the .20's but low positive

coefficients below .20 among boys: irritable temperament, stubbornness, slovenliness, depressed mood or spells, unhappiness, repressed manner, truancy from home, question or diagnosis of encephalitis, and staff notation of unfavorable conduct prognosis.

Two negative correlations of significant size were found, both among girls: "follower,"  $-.28 \pm .06$ , and feeble-minded sibling,  $-.38 \pm .06$ .

With the six sex notations boastful or "show-off" manner showed several meaningful correlations. With overinterest in sex matters the respective correlations among boys and girls were  $.23 \pm .05$  and  $.34 \pm .07$ . With masturbation the coefficients for boys and girls respectively were  $.22 \pm .03$  and  $.19$ . With overinterest in the opposite sex, for which only the girls' coefficient was computed, the substantial correlation of  $.33 \pm .05$  was found. With sex delinquency (coitus), however, both coefficients were negligible.

Among the seven physical or psychophysical notations, all correlations were low or negligible, except possibly the coefficient of very questionable statistical significance,  $.20 \pm .09$ , with question or diagnosis of encephalitis among girls.

With the four home or familial notations all correlations were low or negligible.

CHAPTER LIII

"BOSSY"; "LEADER"; AND "FOLLOWER"

In our data bossy manner was considered as an undesirable conduct problem. The notations "leader" and "follower" were included in the original indexing as behavior traits to be considered neither as personality nor as conduct problems but as a "neutral" trait included for comparative purposes.

Bossy manner toward playmates was noted among 112, or 5.3 per cent, of our 2,113 White boys and among 86, or 7.3 per cent, of our 1,181 White girls. Among girls it appeared to be of considerable clinical importance, its bi-serial correlations with the personality-total and conduct-total being  $.50 \pm .03$  and  $.43 \pm .03$  respectively (Table 106). Among boys the corresponding correlations of  $.32 \pm .03$  and  $.28 \pm .03$  were of moderate size. With the

Other Correlations (Positive to Negative)

Irresponsible, .18 and .17; Victim of sex abuse, .17 (girls); Defiant, .16 and .19; Neurological defect, .16 and .11; Finicky food habits, .15 and .03; Complaining of bad treatment by other children, .15 (boys); Attractive manner, .15 and .06; Contrary, .14 and .18; Swearing (general), .14 (boys); Inattentive in school, .13 and .17; Slovenly, .13 and .16; Daydreaming, .13 and .16; Loitering, .12 and -.03; Clean, .11 and .18; Former convulsions, .11 and -.01; Enuresis, .10 and .17; Truancy from home, .10 and .05; Inefficient in work, play, etc., .09 and .10; Incurable, .09 and .19; Lack of interest in school, .08 and .18; Stuttering, .08 (boys); Staying out late at night, .07 and .11; Truancy from school, .06 and .14; Lues, .06 and -.01; Speech defect, .06 and .10; Overinterest in opposite sex, .06 (girls); Irregular sleep habits, .05 and .02; Smoking, .04 (boys); Bashful, .04 and -.04; Question of change of personality, .04 and .19; Absent-minded, .03 and -.13; Seclusive, .03 and .10; Repressed, .03 and .15; Headaches, .03 and -.09; Discord between parents, .03 and .06; Poor work in school, .02 and .05; Underweight, .01 and .05; Irregular attendance at school, .01 and -.05; Conduct prognosis bad, .00 and .02; Grouped: dull, slow, etc., -.02 and -.01; Slow, dull, -.04 and .01; Gang, -.05 (boys); Refusal to attend school, -.06 and -.09; Vicious home conditions, -.07 and .05; Immoral home conditions, -.08 and -.16; Follower, -.08 and -.16; Brother in penal detention, -.09 and -.06; Oversuggestible, -.09 and .11; Question of hypophrenia, -.11 and -.05; Sex denied entirely, -.12 and -.10; Popular, -.14 and .12; Sex delinquency (coitus), -.14 and .01; Listless, -.16 and -.10; Retardation in school, -.17 and -.08

police-arrest criterion of overt juvenile delinquency its tetra-choric correlations of .02 and -.08 among both sexes were negligible.

Its largest correlations were with unpopularity, the respective coefficients for boys and girls being .36 ± .06 and .54 ± .06. The second highest correlations among both sexes were with boastful or "show-off" manner, the corresponding coefficients being .33 ± .05 and .47 ± .06. Violence among girls also yielded the large correlation of .46 ± .06 but a low positive correlation among boys of .19.

Three conduct problems yielded substantial correlations in the .30's with bossy manner among both sexes: egocentricity, quarrelsomeness, and temper tantrums or display (undifferentiated). Among girls eight conduct and personality problems yielded substantial correlations in the .30's, the corresponding coefficients among boys being of moderate size in the .20's: "spoiled child," temper display, "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated), distractibility, fighting, swearing or bad language (undifferentiated), hatred or jealousy of sibling, and mental conflict. Among girls an additional six personality and conduct problems yielded substantial correlations in the .30's but low coefficients below .20 among boys: object of teasing by other children, sensitiveness over some specific fact, worry over some specific fact, depressed mood or spells, changeable moods or attitudes, and overinterest in sex matters.

Bossy manner showed moderate correlations in the .20's among both sexes for the following eleven undesirable behavior manifestations: selfishness, irritable temperament, "nervousness," restlessness, nail-biting, stubbornness, temper tantrums, disturbing influence in school, lying, fantastical lying, and sensitivity in general. Two conduct problems for which only the boys' correlations were computed also showed moderate correlations in the .20's: threatening violence and teasing other children. Four personality and conduct problems showed moderate correlations in the .20's among boys but low coefficients below .20 among girls: rudeness, destructiveness, crying spells, and inferiority feelings. A large list of nineteen miscellaneous case-record notations showed correlations in the .20's among girls but low coefficients below .20 among boys: "leader," leading others into bad conduct, preference for younger children as playmates, disobedience, bad companions, stealing, excuse-forming attitude, sullenness, sulkiness, laziness, lack of interest or inattentiveness in school studies or employment (undifferentiated), emotional instability, psychoneurotic trends, unhappiness, apprehensiveness, queer behavior, restlessness in sleep, masturbation, and exclusion from school.

Question or diagnosis of encephalitis showed a curious divergence of relationship among the two sexes, its correlation among boys being negative,  $-.27 \pm .07$ , while its correlation among girls

was of positive sign,  $.22 \pm .09$ , though the latter coefficient is of very doubtful statistical significance since it is less than three times its probable error. Lack of initiative and "request for vocational guidance" among girls showed negative correlations of moderate size in the  $-.20$ 's.

Among the six sex notations there were two correlations of significant size with bossy manner among girls,  $.38 \pm .06$  with overinterest in sex matters and  $.24 \pm .06$  with masturbation, the corresponding correlations for boys being low,  $.14$  and  $.10$ .

Among the seven physical or psychophysical disabilities the only meaningful correlations were with question or diagnosis of encephalitis, as noted above.

Among the four home or familial notations all correlations were low or negligible.

The notation patient a leader in group of same age was noted among 152 of our boys, or 7.2 per cent, and among 78 of our girls, or 6.6 per cent. Its correlations with all three criteria of seriousness were low but positive, ranging from  $.05$  to  $.21$  (Table 107).

## Other Correlations (Positive to Negative)

Grouped: disobedient, etc., .19 and .14; Grouped: lack of interest in school, etc., .18 and .15; Disobedient, .18 and .15; Hatred or jealousy of sibling, .18 and .07; Disturbing influence in school, .18 and .18; Smoking, .17 (boys); Bad companions, .15 and .13; Stubborn, .15 and .12; "Nervous," .14 and .12; Truancy from school, .14 and .14; Fighting, .13 and -.07; Loitering, .13 and .11; Truancy from home, .12 and -.07; Sullen, .12 and .12; Slovenly, .12 and -.06; Irresponsible, .12 and .19; Selfish, .11 and .15; Sensitive over specific fact, .11 and .11; Spoiled child, .11 and .12; Sex denied entirely, .11 and .12; Grouped: fighting, etc., .11 and .10; Overinterest in opposite sex, .11 (girls); Temper display, .10 and .14; Swearing (general), .10 (boys); Rude, .10 and .07; Contrary, .09 and .04; Refusal to attend school, .09 and .15; Quarrelsome, .09 and .05; Irregular sleep habits, .09 and -.01; Worry over specific fact, .09 and .05; Clean, .09 and .07; Emotional instability, .08 and .11; Excuse-forming, .08 and .18; Teasing other children, .07 (boys); Preference for younger children, .07 and -.06; Grouped: sensitive or worrisome, etc., .07 and .10; Nail-biting, .06 and .06; Grouped: swearing, etc., .06 and .09; Masturbation, .06 and .15; Incurable, .06 and .17; Exclusion from school, .06 and -.11; Destructive, .05 and -.01; Temper tantrums, .05 and .10; Sex delinquency (coitus), .05 and -.04; Distractible, .05 and .12; Mental conflict, .05 and .08; Discord between parents, .05 and -.02; Complaining of bad treatment by other children, .04 (boys); Crying spells, .04 and .19; Violence, .04 and .12; Bashful, .03 and -.08; Irregular attendance at school, .03 and -.03; Conduct prognosis bad, .02 and -.06; Threatening violence, .02 (boys); Lazy, .02 and -.11;

TABLE 107—Continued

Victim of sex abuse, .02 (girls); Absent-minded, .01 and -.09; Oversuggestible, .01 and -.09; Vocational guidance, .00 and -.01; Finicky food habits, -.00 and .17; Question of encephalitis, -.00 and -.05; Poor work in school, -.01 and -.00; Inferiority feelings, -.01 and .06; Lack of initiative, -.01 and -.11; Inefficient in work, play, etc., -.02 and -.11; Lies, -.02 and -.09; Brother in penal detention, -.02 and -.05; Unhappy, -.03 and .06; Sulky, -.04 and .08; Vicious home conditions, -.05 and -.03; Psychoneurotic, -.05 and -.01; Enuresis, -.06 and .18; Grouped: depressed, etc., -.06 and .12; Speech defect, -.07 and -.19; Sensitive (general), -.07 and .05; Depressed, -.08 and .09; Headaches, -.09 and .15; Stuttering, -.09 (boys); Object of teasing, -.09 and -.19; Question of change of personality, -.09 and .07; Underweight, -.11 and -.06; Question of hypophrenia, -.11 and .19; Apprehensive, -.11 and -.02; Former convulsions, -.12 and -.04; Listless, -.15 and -.14; Slow, dull, -.17 and -.14; Grouped: dull, slow, etc., -.17 and -.17

Omitted—Follower

Its largest correlations were with popularity, the respective coefficients for boys and girls being  $.32 \pm .05$  and  $.40 \pm .07$ . Leading others into bad conduct among boys yielded the substantial correlation of  $.32 \pm .05$  but among girls a low coefficient of .18. Irritable temperament and fantastical lying among girls yielded substantial correlations in the .30's but low positive coefficients below .20 among boys.

"Leader" showed moderate correlations in the .20's among both sexes with the three traits boastful or "show-off" manner, restlessness, and attractive manner and also with running with a gang (calculated for boys only). Two conduct problems among boys—staying out late at night and lack of interest in school—showed moderate correlations in the .20's but negligible coefficients below .20 among girls. Among the girls twelve undesirable manifestations showed moderate correlations in the .20's but among boys low coefficients below .20: bossy manner, egocentricity, changeable moods or attitudes, temper tantrums or display (including irritable temperament, undifferentiated), restlessness in sleep, daydreaming, inattentiveness in school, stealing, lying, defiant attitude, over-interest in sex matters, and unpopularity.

It may seem curious that the notation "leader" shows positive correlations with both of the apparently antithetical traits popularity and unpopularity. This problem was discussed in earlier pages (p. 45 and in the concluding paragraphs of chaps. xx, xxv, and xlvi). These apparently contradictory correlations may, of course, be due to a general inaccuracy in case-record material

of the kind utilized in this study. But the explanation may also be made on a curvilinearity of regression of "leader" with the trait popularity-unpopularity. It may be that a child who tends to be a leader among other children is likely to be both popular and unpopular among his associates, according to the specific relation of a "leader" to another individual child affected by his "leadership." It is interesting to note that the correlations of "follower" with both popularity and unpopularity are very low or negligible, as will be found in Table 108 (p. 511).

"Leader" among boys showed negative correlations of moderate size ranging from  $-.20$  to  $-.32$  with queer behavior and neurological defect (unspecified) and among girls with repressed manner, seclusiveness, retardation in school, feeble-minded sibling, and immoral home conditions.

Among the six sex notations the only correlation of moderate size was with overinterest in sex matters among girls,  $.22 + .07$ . All other correlations in this field were low or negligible, ranging from  $-.05$  to  $.15$ .

Among the seven physical or psychophysical disabilities the only correlation of moderate size was the negative one of  $-.24 + .05$  with neurological defect (unspecified) among boys.

Among the four home or familial notations the largest correlation with "leader" was the negative one,  $-.20 + .07$ , with immoral home conditions among girls, which is of doubtful statistical significance, since it is less than the conventionally accepted "three times its probable error."

Patient a "follower" in group of similar age was noted among 202 cases, or 9.6 per cent, of our 2,113 White boys and among 103 cases, or 8.7 per cent, of our 1,181 White girls. Its correlations with our three criteria of seriousness or "ominousness" were low or negligible, ranging from  $-.03$  to  $.12$  (Table 108). Since almost all its correlation coefficients with other separate case notations were of negligible size (only nine showing coefficients as high as the .20's) it may be concluded that "follower" is of very minor importance from clinical considerations.

The largest positive correlation was the moderate one of  $.29 + .04$  with oversuggestibility among boys, the corresponding coefficient among girls being  $.18$ . Bashfulness showed moderate

Absent-minded, .18 and .03; Changeable moods, .17 and .04; Grouped: "nervous," etc., .16 and .09; Sex denied entirely, .16 and -.08; Poor work in school, .14 and .13; Finicky food habits, .14 and .12; Lack of interest in school, .13 and .14; Refusal to attend school, .13 and .00; Slovenly, .13 and -.06; Smoking, .13 (boys); Restless, .13 and .13; Restless in sleep, .13 and .06; Grouped: dull, slow, etc., .12 and .15; Distractible, .12 and .16; Lazy, .11 and -.04; Lying, .11 and .08; Stealing, .11 and -.03; Apprehensive, .11 and .12; Slow, dull, .11 and .12; Truancy from school, .10 and -.01; Nail-biting, .10 and .13; Enuresis, .09 and .06; Selfish, .09 and .10; Irritable, .09 and -.00; Retardation in school, .09 and .01; Victim of sex abuse, .09 (girls); Grouped: lack of interest in school, etc., .08 and .11; Preference for younger children, .08 and .09; Mental conflict, .08 and .12; Sex delinquency (coitus), .08 and .17; Teasing other children, .07 (boys); Worry over specific fact, .07 and -.04; Complaining of bad treatment by other children, .07 (boys); Unhappy, .07 and -.04; Grouped: sensitive or worrisome, etc., .07 and .03; Grouped: temper, etc., .06 and -.02; Immoral home conditions, .06 and -.11; Vicious home conditions, .06 and -.10; Sullen, .06 and -.02; Loitering, .06 and -.02; Irresponsible, .06 and .08; Inefficient in work, play, etc., .05 and .06; Question of hypochondria, .05 and .09; Grouped: egocentric, etc., .04 and .09; Brother

TABLE 108—Continued

in penal detention, .04 and .00; "Nervous," .04 and .02; Overinterest in sex matters, .04 and -.05; Daydreaming, .04 and -.01; Swearing (general), .04 (boys); Stubborn, .04 and -.11; Disobedient, .03 and .00; Disturbing influence in school, .03 and .01; Rude, .03 and -.09; Sulky, .03 and -.05; Temper display, .03 and .10; Emotional instability, .03 and -.06; Grouped: disobedient, etc., .03 and .08; Exclusion from school, .02 and .04; Leading others into bad conduct, .02 and .09; Fighting, -.00 and -.07; Listless, -.00 and .05; Object of teasing, -.00 and .13; Grouped: depressed, etc., -.00 and -.09; Egocentric, -.01 and .06; Truancy from home, -.01 and -.01; Inferiority feelings, -.02 and .08; Former convulsions, -.02 and -.15; Discord between parents, -.03 and -.12; Destructive, .02 and .06; Hatred or jealousy of sibling, .02 and .09; Staying out late at night, .01 and .01; Masturbation, .01 and -.09; Depressed, .01 and -.19; Irregular sleep habits, .01 and -.08; Sensitive over specific fact, .01 and .06; Unpopular, .01 and -.11; Spoiled child, .01 and .01; Neurological defect, .01 and -.16; Vocational guidance, .01 and -.05; Stuttering, .00 (boys); Underweight, -.03 and -.06; Clean, -.03 and .07; Sensitive (general), -.03 and .03; Inattentive in school, -.04 and .11; Violence, -.04 and -.11; Headaches, -.04 and .02; Grouped: swearing, etc., -.04 and -.03; Conduct prognosis bad, -.05 and .05; Contrary, -.05 and -.18; Overinterest in opposite sex, -.05 (girls); Incorrigible, -.06 and -.07; Queer, -.06 and -.10; Seclusive, -.06 and -.01; Grouped: fighting, etc., -.06 and .04; Temper tantrums, -.07 and -.17; Bossy, -.08 and -.16; Threatening violence, -.08 (boys); Popular, -.08 and .10; Quarrelsome, -.09 and .06; Fantastical lying, -.09 and -.03; Attractive manner, -.10 and .01; Irregular attendance at school, -.10 and -.07; Psychoneurotic, -.12 and -.08; Feeble-minded sibling, -.14 and .07; Question of encephalitis, -.18 and -.11

Omitted—Leader

correlations in the .20's among both sexes. Running with a gang among boys similarly showed the moderate correlation of  $.21 \pm .04$ , the corresponding coefficient for girls not being calculated because of the paucity of girls' cases. Four additional notations among boys showed moderate correlations in the .20's, but low coefficients below .20 among girls: bad companions, excuse-forming attitude, crying spells, and speech defect (other than stuttering). Two notations among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: lack of initiative and lues.

"Follower" showed four negative correlations of moderate size ranging from -.21 to -.29: among boys for question of change of personality and among girls for repressed manner, boastful or "show-off" manner, and defiant attitude.

Among the six sex notations all correlations with "follower" were low or negligible, ranging from -.09 to .17.

Among the seven physical or psychophysical disabilities there were two coefficients of moderate size in the .20's, speech defect (other than stuttering) among boys and lues among girls.

Among the four home or familial notations all correlations were low or negligible, ranging from  $-.12$  to  $.06$ .

A comparison of the corresponding correlations for the presumably antithetical notations "leader" (Table 107) and "follower" (Table 108) shows again the curious statistical phenomenon that many of the coefficients for these antithetical pairs of traits were not of opposite sign and of similar magnitude, as would be supposed if strictly objectively measurable traits were being used but were often of the same sign (though of different magnitude). Among the 118 pairs of corresponding coefficients for the boys in Table 107 ("leader") and Table 108 ("follower") there were 75 pairs of like sign and only 43 of unlike sign. Among 113 pairs of girls' coefficients there were 58 pairs of like sign and 55 of unlike sign. The intercolumnar correlations (Pearson's product-moment) were  $.10 \pm .06$  for boys and  $-.10 \pm .06$  for girls. (A discussion and attempted explanation of this phenomenon may be found in I, 134-35 and 249-50, and in this volume, p. 45, and in the concluding paragraphs of chaps. xx, xxv, and xlvi.)

CHAPTER LIV

SULLENNESS AND SULKINESS

Sullenness and sulkiness appeared to be of little more than moderate importance so far as its correlations with our three criteria of seriousness or "ominousness" are concerned.

Sullenness was noted among 243 of our 2,113 White boys (11.5 per cent) and among 97 of our 1,181 White girls (8.2 per cent). With personality-total and conduct-total the correlations were of only moderate or scarcely substantial size, ranging from .29 to .35 (Table 109). With police arrest its tetrachoric r among boys was moderate, .23 ± .03, and among girls negligible, .08 ± .05.

## Other Correlations (Positive to Negative)

Disturbing influence in school, .19 and .17; Selfish, .19 and .16; Irregular sleep habits, .18 and -.07; Boastful, "show-off," .17 and .14; Question of change of personality, .17 and .19; Lazy, .16 and -.00; Bad companions, .16 and .09; Staying out late at night, .15 and .13; Vicious home conditions, .14 and .14; Teasing other children, .13 (boys); Slowly, .13 and .03; Leader, .12 and .12; Mental conflict, .12 and .13; Inefficient in work, play, etc., .11 and .16; Queer, .11 and .18; Brother in penal detention, .11 and .11; Sex denied entirely, .10 and .07; Sensitive over specific fact, .09 and .17; Inferiority feelings, .09 and -.13; Complaining of bad treatment by other children, .09 (boys); Discord between parents, .08 and .01; Immoral home conditions, .08 and .06; Clean, .08 and -.03; Poor work in school, .08 and .02; Inattentive in school, .07 and .07; Sex delinquency (coitus), .07 and .09; Slow, dull, .07 and .08; Listless, .07 and .15; Emotional instability, .07 and .17; Follower, .06 and -.02; Nail-biting, .05 and .09; Popular, .05 and .03; Grouped: dull, slow, etc., .04 and .07; Apprehensive, .04 and .10; Bashful, .03 and -.05; "Nervous," .03 and .04; Restless in sleep, .03 and .12; Retardation in school, .02 and -.02; Vocational guidance, .00 and -.04; Enuresis, -.00 and -.07; Question of hypochondria, -.00 and .05; Lues, -.00 and .07; Feeble-minded sibling, -.00 and -.05; Headaches, -.01 and .06; Attractive manner, -.01 and -.06; Oversuggestible, -.01 and -.00; Irresponsible, -.01 and -.01; Lack of initiative, -.02 and -.13; Victim of sex abuse, -.03 (girls); Worry over specific fact, -.03 and -.04; Stuttering, -.04 (boys); Question of encephalitis, -.05 and .08; Former convulsions, -.05 and -.08; Psychoneurotic, -.06 and .08; Preference for younger children, -.06 and .10; Neurological defect, -.08 and .11; Underweight, -.09 and .10; Speech defect, -.12 and -.09

Among both sexes, its largest correlations were with defiant attitude, the respective coefficients for boys and girls being  $.41 \pm .04$  and  $.44 \pm .06$ . Rudeness and leading others into bad conduct among girls yielded large correlations in the .40's but among boys only moderate coefficients in the .20's.

Contrariness and stubbornness among both sexes yielded substantial correlations in the .30's. Threatening violence, for which only the boys' coefficient was computed, also yielded the substantial correlation of  $.32 \pm .05$ . Swearing or bad language (undifferentiated) among boys yielded the substantial correlation of  $.34 \pm .04$  but among girls a low coefficient of .19. Nine undesirable behavior notations among girls yielded substantial correlations in the .30's with corresponding moderate coefficients in the .20's among boys: sulkiness, disobedience, egocentricity, lack of interest in school, quarrelsomeness, temper tantrums or display (undifferentiated), unhappiness, stealing, and staff notation of unfavorable conduct prognosis. Two additional behavior problems among girls yielded substantial correlations in the .30's but low

positive coefficients below .20 among boys: "spoiled child" and temper tantrums.

Eight notations showed moderate correlations in the .20's among both sexes: incurrigibility, violence, irritable tempera-ment, lying, fantastical lying, truancy from school, exclusion from school, and repressed manner. Three notations for which only boys' correlations were computed—running with a gang, smoking, and swearing in general—and the notation overinterest in the op-posite sex, for which only the girls' coefficient was computed, also showed moderate coefficients in the .20's. Five undesirable behavior traits showed moderate correlations in the .20's among boys but low coefficients below .20 among girls: hatred or jeal-ousy of sibling, truancy from home, destructiveness, excuse-forming attitude, and unpopularity. Seventeen personality and conduct problems among girls showed moderate correlations in the .20's but low coefficients below .20 among boys: refusal to attend school, fighting, temper display, bossy manner, seclusiveness, absent-mindedness, distractibility, restlessness, depressed mood or spells, daydreaming, changeable moods or attitudes, sensitiveness in gen-eral, object of teasing by other children, crying spells, finicky food habits, masturbation, and overinterest in sex matters.

Sullenness among girls showed negative correlations of mod-erate size in the -.20's with loitering or wandering and irregular attendance at school.

Among the six sex notations there were three correlations of moderate size in the .20's among girls: masturbation, overin-terest in sex matters, and (calculated for girls only) overinter-est in the opposite sex.

Among the seven physical or psychophysical notations and the four home or familial notations, all correlations were low or negligible, ranging from -.12 to .14.

Sulkiness or pouting was noted among 112, or 5.3 per cent, of our boys and among 68, or 5.8 per cent, of our girls. With per-sonality-total and conduct-total its bi-serial correlations were of moderate size in the .20's (Table 110). With police arrest its tetrachoric correlations for both sexes were low, .16 and .07 for boys and girls respectively.

The only notation among both sexes yielding substantial

## Other Correlations (Positive to Negative)

Irritable, .19 and .19; Restless in sleep, .19 and .14; Selfish, .18 and -.02; Overinterest in sex matters, .18 and .11; Spoiled child, .17 and .10; Absent-minded, .17 and .14; Refusal to attend school, .17 and .10; Fighting, .17 and .09; Bad companions, .16 and .17; Destructive, .16 and .18; Enuresis, .16 and .09; Smoking, .16 (boys); Sensitive over specific fact, .16 and .15; Popular, .16 and .17; Restless, .15 and .14; Grouped: swearing, etc., .15 and .06; Grouped: lack of interest in school, etc., .15 and .03; Vicious home conditions, .15 and -.07; Complaining of bad treatment by other children, .15 (boys); Truancy from home, .15 and .14; Teasing other children, .15 (boys); Staying out late at night, .14 and .03; Swearing (general), .14 (boys); Threatening violence, .14 (boys); Repressed, .14 and .11; Grouped: egocentric, etc., .13 and .19; Conduct prognosis bad, .13 and .01; Lazy, .13 and .12; Lack of interest in school, .13 and .03; Finicky food habits, .13 and .15; Loitering, .12 and .09; Gang, .12 (boys); Slovenly, .12 and .13; Truancy from school, .12 and .15; Question of change of personality, .12 and .17; Distractable, .12 and .14; Preference for younger children, .12 and .08; Seclusive, .11 and .08; Incurable, .11 and .14; Stealing, .10 and .14; "Nervous," .10 and .04; Emotional instability, .10 and .14; Exclusion from school, .10 and .19; Attractive manner, .09 and .10; Inattentive in school, .09 and .01; Masturbation, .08 and .18; Hatred or jealousy of sibling, .08 and .04; Sex denied entirely, .08 and -.07; Discord between parents, .07 and .01; Mental conflict, .07 and .17; Listless, .07 and .10; Daydreaming, .07 and .18; Bashful, .06 and .06; Clean, .06 and .14; Overinterest in opposite sex, .06 (girls); Former convulsions, .05 and -.01; Inferiority feelings, .05 and .09; Oversuggestible, .05 and .11; Nail-biting, .04 and .02; Question of hypochondria, .04 and .01; Headaches, .03 and .05; Follower, .03 and -.05; Stuttering, .03 (boys); Irresponsible, .03 and .06; Slow, dull, .02 and .03; Poor work in school, .02 and .12; Grouped: dull, slow, etc., .02 and .06; Speech defect, .01 and -.07; Retardation in school, .01 and .03; Lack of initiative, .01 and -.04; Victim of sex abuse, -.00 (girls); Vocational guidance, -.01 and -.14; Irregular attendance at school, -.02 and .05; Immoral home conditions, -.03 and .00; Neurological defect, -.03 and .04; Psychoneurotic, -.03 and .08; Leader, -.04 and .08; Question of encephalitis, -.12 and .09; Lues, -.13 and -.06; Underweight, -.17 and -.07; Brother in penal detention, -.19 and .09

correlations in the .30's was the "larger grouping," disobedience or incorrigibility (including defiant attitude, stubbornness, and contrariness, undifferentiated). Among girls three behavior problems yielded substantial correlations in the .30's and moderate coefficients in the .20's among boys: sullenness, contrariness, and "nervousness" or restlessness (including irritable temperament and changeable moods, undifferentiated). Six additional undesirable behavior problems yielded substantial correlations in the .30's among girls but low coefficients below .20 among boys: sensitive-ness in general, changeable moods or attitudes, unhappiness, queer behavior, temper tantrums, and excuse-forming attitude.

Sulkiness showed moderate correlations in the .20's among

both sexes with six conduct and personality problems: rudeness, stubbornness, defiant attitude, temper display, boastful or "show-off" manner, and crying spells. Five conduct and personality problems among boys showed moderate correlations in the .20's, but low coefficients below .20 among girls: disobedience, violence, disturbing influence in school, apprehensiveness, and sex delinquency (coitus). Among girls eleven undesirable behavior traits showed moderate correlations in the .20's but low coefficients below .20 among boys: quarrelsomeness, egocentricity, bossy manner, leading others into bad conduct, depressed mood or spells, inefficiency in work, play, etc., object of teasing by other children, worry over some specific fact, lying, fantastical lying, and unpopularity.

Two case-record notations showed negative correlations of moderate size in the -.20's, irregular sleep habits among girls and feeble-minded sibling among both sexes.

Among the six sex notations the only correlation of meaningful size with sulkiness was the statistically questionable coefficient of  $.20 \pm .07$  with sex delinquency (coitus) among boys.

Among the seven physical or psychophysical disabilities and the four home or familial notations all correlations were low or negligible.

CHAPTER LV

HATRED OR JEALOUSY FOR SIBLING

Hatred or jealousy for sibling, step-sibling, foster-sibling, etc., was noted among 95 of our 2,113 White boys, or 4.5 per cent, and among 58 of our 1,181 White girls, or 4.9 per cent. Its bi-serial correlations (in the .40's) with the personality-total were fairly large and also substantial (in the .30's) with conduct-total (Table 111). Its tetrachoric correlations with the police-arrest criterion of overt juvenile delinquency, however, were low.

## Other Correlations (Positive to Negative)

Complaining of bad treatment by other children, .19 (boys); Discord between parents, .19 and -.05; Leader, .18 and .07; Object of teasing, .18 and .15; Psychoneurotic, .18 and .18; Teasing other children, .18 (boys); Inattentive in school, .18 and .11; Bad companions, .17 and .17; Lazy, .17 and .17; Lying, .17 and .15; Truancy from school, .17 and .04; Masturbation, .17 and .15; Exclusion from school, .17 and .04; Swearing (general), .16 (boys); Disobedient, .15 and .12; Bashful, .15 and .04; Refusal to attend school, .14 and .14; Apprehensive, .14 and .16; Clean, .13 and -.01; Distractible, .13 and .15; Loitering, .12 and -.09; Stealing, .12 and .10; Truancy from home, .12 and .09; Neurological defect, .12 and .09; Staying out late at night, .11 and .08; Fighting, .11 and .18; Poor work in school, .10 and .04; Temper tantrums, .09 and .15; Smoking, .09 (boys); Gang, .09 (boys); Incurable, .08 and -.01; Sulky, .08 and .04; Conduct prognosis bad, .08 and -.05; Immoral home conditions, .08 and .00; Overinterest in opposite sex, .08 (girls); Irresponsible, .07 and .10; Inefficient in work, play, etc., .07 and .18; Disturbing influence in school, .06 and -.02; Lues, .06 and -.08; Popular, .05 and .08; Underweight, .04 and .02; Speech defect, .04 and -.10; Slow, dull, .03 and .18; Enuresis, .03 and .09; Finicky food habits, .03 and .17; Irregular sleep habits, .02 and .06; Lack of initiative, .02 and .13; Stuttering, .02 (boys); Follower, .02 and .09; Over-suggestible, .00 and -.06; Preference for younger children, -.00 and .01; Victim of sex abuse, -.00 (girls); Unpopular, -.01 and .16; Grouped: dull, slow, etc., -.01 and -.09; Listless, -.03 and .04; Absent-minded, -.04 and .19; Emotional instability, -.04 and .15; Irregular attendance at school, -.05 and -.12; Question of change of personality, -.06 and .12; Sex delinquency (coitus), -.07 and -.09; Question of encephalitis, -.08 and -.11

Among both boys and girls its largest correlations were with inferiority feelings, the respective coefficients being .36 + .05 and .43 + .08. Fantastical lying among girls also yielded a large correlation of .40 + .07 but a low coefficient of .16 among boys.

Three conduct and personality problems—rudeness, destructiveness, and queer behavior—also yielded substantial correlations in the .30's among boys and moderate correlations in the .20's among girls. Contrariness and daydreaming among boys similarly yielded substantial correlations in the .30's but negligible coefficients among girls. Six personality and conduct problems among girls yielded substantial correlations in the .30's with corresponding moderate coefficients in the .20's among boys: egocentricity, bossy manner, quarrelsomeness, temper tantrums or display (undifferentiated), sensitiveness over some specific fact, and depressed mood or spells. Among girls five additional personality and conduct difficulties yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: stubbornness, tem-

per display, sensitiveness in general, restlessness in sleep, and overinterest in sex matters.

Six personality and conduct problems consistently showed moderate correlations in the .20's: selfishness, boastful or "show-off" manner, irritable temperament, swearing or bad language (undifferentiated), mental conflict, and (calculated for boys only) threatening violence. Ten personality problems among boys showed moderate correlations in the .20's but low positive coefficients below .20 among girls: "spoiled child," sullenness, defiant attitude, violence, excuse-forming attitude, lack of interest in school, seclusiveness, unhappiness, attractive manner, and sex misbehavior denied entirely. Eleven miscellaneous notations among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: leading others into bad conduct, slovenliness, repressed manner, "nervousness," restlessness, changeable moods or attitudes, crying spells, worry over some specific fact, nail-biting, former convulsions, and headaches.

Hatred or jealousy of sibling showed negative correlations of moderate size ranging from  $-.20$  to  $-.32$  with four notations, all among girls: question of hypophrenia, retardation in school, vicious home conditions, and brother in penal detention.

Among the six sex notations there were two correlations of significant size, overinterest in sex matters among girls,  $.34 \pm .07$ , and sex misbehavior denied entirely among boys,  $.20 \pm .06$ .

Among the seven physical or psychophysical notations all correlations were negligible, ranging from  $-.11$  to  $.12$ .

Among the four home or familial notations there were two negative correlations of moderate size, both among girls: vicious home conditions,  $-.25 \pm .08$ , and brother in penal detention,  $-.32 \pm .07$ .

CHAPTER LVI

SCHOOL NOTATIONS: POOR WORK, RETARDATION,  
EXCLUSION

The three frequently appearing school notations considered in this chapter were not counted as either personality or conduct problems. Poor work in school and retardation in school showed only minor correlations with our three criteria of seriousness, but exclusion from school appeared to be of considerable importance with respect to conduct deviation.

Poor work in school was noted among 632 cases, or 29.9 per cent, of our 2,113 White boys and among 319 cases, or 27.0 per cent, of our 1,181 White girls. With the personality-total its bi-serial correlations of  $.21 \pm .02$  and  $.18 \pm .03$  among boys and girls respectively indicate a palpable relationship (Table 112). Its bi-serial correlations with the conduct-total among both sexes and its

## Other Correlations (Positive to Negative)

Irresponsible, .19 and .09; Object of teasing, .19 and .14; Daydreaming, .18 and .06; Teasing other children, .17 (boys); Overinterest in opposite sex, .17 (girls); Seclusive, .16 and .19; Spoiled child, .16 and .10; Refusal to attend school, .14 and .16; Complaining of bad treatment by other children, .14 (boys); Unhappy, .14 and .09; Follower, .14 and .13; Oversuggestible, .13 and .06; Attractive manner, .13 and .08; Speech defect, .13 and .12; Boastful, "show-off," .12 and .14; Grouped: "nervous," etc., .12 and .11; Grouped: disobedient, etc., .12 and .07; Fantastical lying, .11 and .11; Loitering, .11 and .08; Rude, .11 and .09; Bashful, .11 and .06; Listless, .11 and .14; Mental conflict, .11 and .06; Conduct prognosis bad, .11 and .01; Crying spells, .10 and .08; Disobedient, .10 and .16; Hatred or jealousy of sibling, .10 and .04; Contrary, .09 and .01; Question of change of personality, .09 and .06; Irritable, .09 and .06; Sensitive (general), .09 and .09; Vocational guidance, .09 and .11; Leading others into bad conduct, .08 and .10; Quarrelsome, .08 and .05; Slowly, .08 and .12; Sullen, .08 and .02; Headaches, .08 and .13; Apprehensive, .07 and .12; Sensitive over specific fact, .07 and .07; Worry over specific fact, .07 and -.03; Sex denied entirely, .07 and .01; Grouped: sensitive or worrisome, etc., .07 and .10; Grouped: depressed, etc., .07 and .08; Fighting, .06 and .06; Incurable, .06 and .08; Temper display, .06 and -.04; Queer, .06 and .08; Selfish, .05 and -.02; Smoking, .05 (boys); Truancy from school, .05 and .06; Excuse-forming, .05 and .16; "Nervous," .05 and .14; Restless in sleep, .05 and .02; Grouped: fighting, etc., .05 and -.01; Victim of sex abuse, .05 (girls); Finicky food habits, .04 and -.02; Lying, .04 and .04; Gang, .04 (boys); Irregular sleep habits, .04 and .04; Clean, .04 and -.06; Former convulsions, .04 and -.01; Bad companions, .04 and -.10; Underweight, .04 and .01; Changeable moods, .03 and .04; Depressed, .03 and .05; Bossy, .02 and .05; Sulky, .02 and .12; Swearing (general), .02 (boys); Threatening violence, .02 (boys); Repressed, .02 and .09; Popular, .02 and -.01; Question of encephalitis, .02 and -.07; Vicious home conditions, .02 and -.03; Destructive, .01 and .00; Stubborn, .01 and -.06; Violence, .01 and .01; Masturbation, .01 and -.09; Brother in penal detention, .01 and -.08; Discord between parents, .01 and -.11; Grouped: temper, etc., .01 and .04; Grouped: swearing, etc., .00 and .03;

TABLE 112—Continued

Tuancy from home,  $-.00$  and  $-.09$ ; Defiant,  $-.00$  and  $-.01$ ; Enuresis,  $-.01$  and  $-.13$ ; Stealing,  $-.01$  and  $-.05$ ; Emotional instability,  $-.01$  and  $-.02$ ; Retardation in school,  $-.01$  and  $.06$ ; Leader,  $-.01$  and  $-.00$ ; Grouped: egocentric, etc.,  $-.01$  and  $.02$ ; Nail-biting,  $-.02$  and  $-.10$ ; Neurological defect,  $-.03$  and  $.06$ ; Overinterest in sex matters,  $-.05$  and  $.04$ ; Egocentric,  $-.06$  and  $.04$ ; Lues,  $-.06$  and  $.13$ ; Feeble-minded sibling,  $-.07$  and  $.04$ ; Temper tantrums,  $-.08$  and  $.05$ ; Psychoneurotic,  $-.08$  and  $-.01$ ; Stuttering,  $-.08$  (boys); Sex delinquency (coitus),  $-.11$  and  $-.19$

tetrachoric  $r$  with police arrest among boys were low or negligible, ranging from  $-.04$  and  $.11$ , but among girls it showed a curious negative correlation,  $-.26 \pm .04$ , with police arrest.

Its highest correlations were with lack of interest in school, with respective coefficients of  $.32 \pm .03$  and  $.42 \pm .04$  among boys and girls. With two behavior problems it yielded substantial correlations in the .30's for girls and moderate coefficients in the .20's for boys: distractibility and disturbing influence in school. Staying out late at night yielded divergent coefficients of  $.07$  and  $.34 \pm .04$ .

Nine miscellaneous behavior notations showed moderate correlations ranging from .20 to .30 for both sexes: inattentiveness in school, inefficiency in work, play, etc., listlessness, lack of initiative, laziness, absent-mindedness, dull or slow manner (including listlessness and lack of initiative, undifferentiated), question of hypophrenia, and preference for younger children as playmates. Irregular attendance at school among boys showed the moderate correlation of  $.20 \pm .03$  but the negligible coefficient of  $.03$  among girls. Three miscellaneous notations among girls showed moderate correlations in the .20's but low positive coefficients below .20 among boys: exclusion from school, inferiority feelings, and unpopularity.

The only significant negative correlation with poor work in school was with immoral home conditions among girls,  $-.26 \pm .04$ .

Among the six sex notations and the seven physical or psychophysical disabilities all correlations were low or negligible, ranging from  $-.19$  to  $.17$ .

Among the four home or familial notations the only significant negative correlation was with immoral home conditions among girls,  $-.26 \pm .04$ , as noted above.

Retardation in school (which presumably will amount to two years or more at the age of 16) was found among 878, or 41.6 per cent, of our White boys and among 474, or 40.1 per cent, of our White girls and was one of the most frequent case-record notations in our data. Its negligible relationship with poor work in school, the tetrachoric correlations being only  $-.01$  and  $.06$ , is curious and unexpected. It appears from our data to be of almost negligible importance as an indicator of personality or conduct deviation, the correlations with our three criteria of seriousness or "ominousness" ranging from  $-.14$  to  $.13$  (Table 113).

## Other Correlations (Positive to Negative)

Oversuggestible, .16 and .04; Lues, .12 and .11; Truancy from school, .10 and -.08; Underweight, .09 and .16; Follower, .09 and .01; Violence, .08 and -.02; Speech defect, .08 and .12; Brother in penal detention, .07 and .09; Leading others into bad conduct, .07 and .08; Former convulsions, .05 and -.00; Distractible, .05 and .14; Threatening violence, .05 (boys); Swearing (general), .05 (boys); Slowly, .05 and -.01; Disturbing influence in school, .05 and -.02; Disobedient, .04 and -.06; Incurable, .04 and -.01; Temper display, .04 and -.04; Apprehensive, .04 and -.04; Conduct prognosis bad, .04 and .06; Sullen, .02 and -.02; Exclusion from school, .02 and .05; Headaches, .02 and -.07; Object of teasing, .01 and .05; Sulky, .01 and .03; Staying out late at night, .01 and -.09; Fighting, .01 and -.05; Complaining of bad treatment by other children, .00 (boys); Enuresis, -.00 and .04; Destructive, -.01 and -.05; Stealing, -.01 and -.04; Crying spells, -.01 and -.09; Poor work in school, -.01 and .06; Question of encephalitis, -.01 and .09; Grouped: fighting, etc., -.02 and -.07; Stuttering, -.02 (boys); Listless, -.02 and -.01; Gang, -.02 (boys); Refusal to attend school, -.03 and -.09; Truancy from home, -.03 and -.05; Overinterest in sex matters, -.03 and -.15; Grouped: temper, etc., -.03 and -.05; Grouped: swearing, etc., -.03 and .06; Restless in sleep, -.04 and -.11; Nail-biting, -.04 and -.05; Bashful, -.05 and -.05; Excuse-forming, -.05 and -.10; Neurological defect, -.05 and -.06; Grouped: disobedient, etc., -.05 and -.03; Grouped: lack of interest in school, etc., -.05 and -.07; Overinterest in opposite sex, -.05 (girls); Seclusive, -.06 and -.07; Lack of initiative, -.06 and -.06; Temper tantrums, -.06 and -.03; Lack of interest in school, -.06 and -.04; Inefficient in work, play, etc., -.07 and -.02; "Nervous," -.07 and -.14; Restless, -.08 and -.02; Queer, -.08 and -.18; Quarrelsome, -.08 and -.09; Lying, -.08 and -.11; Loitering, -.08 and .03; Inattentive in school, -.08 and -.10; Fantastical lying, -.09 and -.10; Teasing other children, -.09 (boys); Smoking, -.09 (boys); Absent-minded, -.09 and .08; Sex denied entirely, -.09 and .03; Emotional instability, -.10 and -.17; Repressed, -.10 and -.13; Unpopular, -.10 and -.05; Rude, -.11 and -.11; Stubborn, -.11 and -.06; Sex delinquency (coitus), -.11 and -.02; Irritable, -.11 and -.11; Unhappy, -.11 and -.12; Grouped: "nervous," etc., -.11 and -.15; Sensitive (general), -.12 and -.14; Irregular sleep habits, -.12 and -.14; Victim of sex abuse, -.12 (girls); Contrary, -.13 and -.13; Selfish, -.13 and -.18; Changeable moods, -.13 and -.13; Immoral home conditions, -.13 and .11; Discord between parents, -.13 and -.05; Masturbation, -.14 and -.15; Finicky food habits, -.14 and -.11; Question of change of personality, -.15 and -.10; Boastful, "show-off," -.17 and -.08; Bossy, -.17 and -.08; Defiant, -.17 and -.17; Popular, -.18 and -.12

Its largest correlations were with question of hypophrenia, the respective coefficients for boys and girls being  $.55 \pm .02$  and  $.48 \pm .03$ . Positive correlations of substantial size in the .30's were found among girls for slow or dull manner and feeble-minded sibling, the corresponding coefficients for boys being of moderate size in the .20's. Three additional notations showed moderate positive correlations in the .20's among girls but low coefficients below .20 among boys: irregular attendance at school, preference for younger children as playmates, and vicious home conditions.

Retardation in school showed a relatively large number of negative correlations of statistically significant magnitude. Worry over some specific fact and "request for vocational guidance" yielded substantial negative correlations in the -.30's among both sexes. Mental conflict and "leader" among girls yielded substantial negative correlations in the -.30's but low negative coefficients less than -.20 among boys.

Psychoneurotic trends and daydreaming showed moderate negative correlations in the -.20's among both sexes. The two "desirable" traits, attractive manner and clean habits, showed moderate negative correlations in the -.20's among boys but low coefficients less than -.20 among girls. Ten notations, chiefly personality problems, among girls showed negative correlations in the -.20's but low negative or negligible coefficients less than  $\pm .20$  among boys: egocentricity, "spoiled child", hatred or jealousy of sibling, laziness, irresponsibility, inferiority feelings, depressed mood or spells, sensitiveness or worrisomeness (undifferentiated), sensitiveness over some specific fact, and bad companions. It is curious that laziness shows negative correlations of  $-.19$  and  $-.20 \pm .05$  with retardation in school, in view of the fact that it was correlated positively to a statistically significant degree with poor work in school, as noted above, those correlations being  $.30 \pm .03$  and  $.21 \pm .05$  among boys and girls respectively.

Among the six sex notations and among the seven physical or psychophysical disabilities all correlations with retardation in school were low or negligible, ranging from  $-.15$  to  $.16$ .

Among the four home or familial notations, the only correlation of significant size was the moderate positive one of  $.21 \pm .05$  with vicious home conditions among girls.

Exclusion, expulsion, or suspension from school was noted among 204, or 9.7 per cent, of our 2,113 White boys and among 71, or 6.0 per cent, of our 1,181 White girls. In contrast with the two school notations previously discussed in this chapter, exclusion from school appears to be of definite clinical significance as an indicator of conduct deviation, its bi-serial correlations with the conduct-total being  $.49 \pm .02$  and  $.56 \pm .03$  for boys and girls respectively (Table 114). Among boys its correlations with

## Other Correlations (Positive to Negative)

Victim of sex abuse, .19 (girls); Egocentric, .18 and .13; Grouped: egocentric, etc., .18 and .09; Hatred or jealousy of sibling, .17 and .04; Enuresis, .16 and .17; Staying out late at night, .16 and .08; Nail-biting, .15 and .18; Smoking, .15 (boys); Oversuggestible, .15 and .14; Bad companions, .14 and .02; Irresponsible, .14 and .16; Gang, .13 (boys); Former convulsions, .11 and .10; Sulky, .10 and .19; Temper display, .10 and .03; Irritable, .10 and .04; Inferiority feelings, .10 and .08; Popular, .09 and .03; Slovenly, .08 and .13; Daydreaming, .08 and .17; Irregular attendance at school, .08 and .08; Speech defect, .08 and -.04; Lazy, .07 and .13; Sex delinquency (coitus), .07 and .18; Depressed, .07 and .10; Restless in sleep, .07 and .16; Leader, .07 and -.11; Clean, .06 and -.01; Underweight, .06 and .14; Irregular sleep habits, .05 and .12; Brother in penal detention, .05 and -.06; Crying spells, .04 and

TABLE 114—Continued

.15; Grouped: depressed, etc., .04 and .11; Spoiled child, .03 and .09; Psychoneurotic, .02 and .12; Retardation in school, .02 and .05; Follower, .02 and .04; Discord between parents, .02 and -.02; Selfish, .01 and .08; Apprehensive, .01 and .05; Finicky food habits, .00 and .14; Vicious home conditions, .00 and .10; Seclusive, -.00 and .15; Sensitive over specific fact, -.01 and .11; Attractive manner, -.01 and .09; Vocational guidance, -.01 and -.13; Listless, -.02 and .05; Sensitive (general), -.04 and .02; Lues, -.04 and .09; Grouped: sensitive or worrisome, etc., -.06 and .13; Repressed, -.07 and .03; Slow, dull -.08 and -.06; Unhappy, -.08 and .08; Grouped: dull, slow, etc., -.09 and .01; Immoral home conditions, -.10 and .12; Sex denied entirely, -.11 and -.08; Lack of initiative, -.16 and .07; Stuttering, -.16 (boys); Feeble-minded sibling, -.17 and -.06

personality-total and police arrest may be considered as substantial, the respective coefficients being  $.32 \pm .02$  and  $.33 \pm .03$ . Among girls the corresponding correlations,  $.16 \pm .04$  and  $.22 \pm .06$ , were less meaningful. The children in our study comprising the group falling under the rubric exclusion from school are not of homogeneous character. While the principal cause for this exclusion among our cases appeared to be for reasons of conduct disturbing to school routine, in many cases exclusion was due to an inability to learn and in some instances because of some physical disability rendering the child unable to be adequately cared for in the public schools.

Its highest correlations were with disturbing influence in school, the coefficient being  $.51 \pm .03$  for both boys and girls. Three conduct problems among girls yielded large correlations in the .40's and moderate coefficients in the .30's among boys: violence, destructiveness, and leading others into bad conduct. Among girls an additional three notations similarly yielded large correlations in the .40's but only moderate coefficients in the .20's among boys: fighting, lying, and question or diagnosis of encephalitis.

Four conduct notations yielded uniformly substantial correlations in the .30's: incorrigibility, rudeness, staff notation of unfavorable conduct prognosis, and (calculated for girls only) overinterest in the opposite sex. Five conduct and personality problems yielded substantial correlations in the .30's among girls and moderate coefficients in the .20's among boys: disobedience, stealing, swearing or bad language (undifferentiated), temper tantrums, and emotional instability. Seven notations among girls

yielded substantial correlations in the .30's but low positive coefficients below .20 among boys: restlessness, distractibility, question of change of personality, mental conflict, object of teasing by other children, unpopularity, and neurological defect (unspecified).

Eight conduct problems showed moderate correlations ranging from .20 to .30 with exclusion from school among both sexes: defiant attitude, sullenness, quarrelsomeness, truancy from school, truancy from home, inattentiveness in school, overinterest in sex matters, and masturbation. Four behavior problems for which only the boys' correlations were computed also showed moderate correlations in the .20's: swearing in general, teasing other children, complaining of bad treatment by other children, and threatening violence. Five undesirable behavior manifestations among boys showed moderate correlations in the .20's but low positive coefficients below .20 among girls: refusal to attend school, contrariness, loitering or wandering, boastful or "show-off" manner, and excuse-forming attitude. Among girls fourteen miscellaneous notations showed moderate correlations in the .20's but low coefficients below .20 among boys: stubbornness, changeable moods or attitudes, queer behavior, "nervousness," question of hypophrenia, lack of interest in school, poor work in school, inefficiency in work, play, etc., absent-mindedness, worry over some specific fact, bossy manner, fantastical lying, preference for younger children as playmates, and headaches.

Only one notation, bashfulness, showed a negative correlation of moderate size with exclusion from school,  $-.20 \pm .04$  among boys.

Among the six sex notations overinterest in the opposite sex, for which only the girls' correlation was computed, showed the substantial correlation of  $.33 \pm .06$ . Overinterest in sex matters and masturbation showed moderate correlations in the .20's among both sexes.

Among the seven physical or psychophysical notations question or diagnosis of encephalitis yielded the fairly large correlation of  $.48 \pm .08$  among girls and a corresponding moderate coefficient of  $.24 \pm .06$  among boys. Neurological defect (unspecified) among girls yielded the fairly substantial correlation of  $.30 \pm .06$ .

Among the four home or familial notations all correlations were low or negligible, ranging from  $-.10$  to  $.12$ .

CHAPTER LVII

ATTRACTIVE MANNER

Attractive manner was one of the four "desirable" behavior traits which were noted with sufficient frequency in our case-record material to justify correlational treatment. The other three "desirable" behavior notations, it will be recalled, were popularity (Table 28), clean habits (Table 90), and "leader" (Table 107). Attractive manner was noted among 307 of our 2,113 White boys, or 14.5 per cent, and among 165 of our 1,181 White girls, or 14.0 per cent. Its correlations with our three criteria of seriousness were low or negligible, ranging from -.08 to .16 (Table 115).

## Other Correlations (Positive to Negative)

Boastful, "show-off," .19 and .09; Lazy, .19 and .05; Discord between parents, .19 and .14; Vocational guidance, .17 and .18; Fantastical lying, .16 and .12; Bossy, .15 and .06; Depressed, .15 and .05; Unhappy, .15 and .02; Grouped: depressed, etc., .14 and .07; Question of encephalitis, .14 and .09; Question of change of personality, .14 and .06; Inattentive in school, .14 and .02; Bad companions, .13 and -.01; Contrary, .13 and .04; Irregular sleep habits, .13 and .07; Poor work in school, .13 and .08; Inferiority feelings, .12 and -.10; Masturbation, .12 and .05; Teasing other children, .12 (boys); Defiant, .11 and .07; Loitering, .11 and .01; Selfish, .11 and .02; Excuse-forming, .10 and .05; Inefficient in work, play, etc., .10 and .06; Finicky food habits, .09 and .14; Leading others in bad conduct, .09 and -.09; Nail-biting, .09 and .06; Rude, .09 and .06; Smoking, .09 (boys); Stubborn, .09 and -.09; Sulky, .09 and .10; Apprehensive, .09 and -.02; Grouped: lack of interest in school, etc., .08 and .09; Complaining of bad treatment by other children, .08 (boys); Mental conflict, .08 and -.01; Lack of initiative, .08 and .04; Overinterest in sex matters, .08 and .19; Slovenly, .08 and -.04; Irresponsible, .08 and .12; Disturbing influence in school, .08 and -.02; Disobedient, .07 and .04; Lying, .07 and .13; Distractible, .07 and .08; Queer, .07 and -.05; Neurological defect, .07 and -.03; Restless in sleep, .06 and .03; Restless, .06 and .05; Crying spells, .06 and .10; Destructive, .05 and -.06; Grouped: disobedient, etc., .05 and -.05; Victim of sex abuse, .05 (girls); Grouped: swearing, etc., .04 and .09; Immoral home conditions, .04 and .15; Changeable moods, .04 and .02; Repressed, .04 and .03; Incurable, .04 and -.04; "Nervous," .03 and .07; Grouped: egocentric, etc., .02 and -.02; Grouped: dull, slow, etc., .02 and -.11; Grouped: "nervous," etc., .02 and .08; Brother in penal detention, .02 and .06; Speech defect, .02 and .06; Seclusive, .02 and -.09; Bashful, .02 and .10; Truancy from school, .02 and .12; Swearing (general), .02 (boys); Staying out late at night, .02 and .02; Refusal to attend school, .02 and -.11; Lack of interest in school, .02 and .15; Temper display, .01 and .02; Threatening violence, .01 (boys); Truancy from home, .01 and -.08; Stealing, .00 and -.01; Object of teasing, -.00 and .08; Exclusion from school, -.01 and .09; Quarrelsomeness, -.01 and -.08; Enuresis, -.01 and -.02; Sullen, -.01 and -.06; Slow, dull, -.02 and -.11; Emotional instability, -.02 and .10; Oversuggestible, -.03 and .06; Temper tantrums, -.03 and -.07; Gang, -.03 (boys); Overinterest in opposite sex, -.03 (girls); Irritable, -.04 and .02; Conduct prognosis bad, -.04 and -.10; Preference for younger children, -.04 and -.09; Question of hypophrenia, -.04 and -.18; Grouped: fighting, etc., -.04 and -.02; Grouped: temper, etc., -.06 and -.02; Fighting, -.07 and .02; Violence, -.08 and .09; Egocentric, -.09 and -.01; Follower, -.10 and .01; Feeble-minded sibling, -.10 and -.06; Lues, -.12 and -.09; Psychoneurotic, -.12 and -.11; Stuttering, -.14 (boys); Sex delinquency (coitus), -.14 and -.13

Its largest correlations (in the .30's) among both sexes were found for popularity and clean habits.

Moderate coefficients in the .20's among both sexes were found for four notations: "leader," "spoiled child," "worry over some specific fact," and vicious home conditions. Eight notations among boys showed moderate correlations in the .20's but low or negligible coefficients below .20 among girls: sensitiveness in general, sensitiveness over some specific fact, hatred or jealousy of sibling, absent-mindedness, sex misbehavior denied entirely, former convulsions, headaches, and underweight condition. Among girls daydreaming and irregular attendance at school showed moderate correlations in the .20's but among boys low or negligible coefficients below .20.

Attractive manner showed three negative correlations of statistically significant size. Listlessness among girls yielded the substantial negative correlation of  $-.34 \pm .05$  but a negligible coefficient of .06 among boys. Retardation in school among boys and unpopularity among girls showed moderate negative correlations in the -.20's.

Attractive manner showed the moderate positive correlation of  $.25 \pm .05$  with sex misbehavior denied entirely among boys. All other correlations with sex notations were low or negligible.

Among the seven physical or psychophysical disabilities the only correlation of significant size was with underweight condition among boys,  $.26 \pm .03$ .

Among the four home or familial notations moderate positive correlations in the .20's were found for vicious (not "immoral") home conditions among both sexes.

## CHAPTER LVIII

### STUTTERING OR STAMMERING

In view of the widespread belief among speech pathologists that the psychologic components in stuttering or stammering are important, it seems feasible to allot a separate chapter to its consideration. Although its correlation with speech defect (other than stuttering) is substantial,  $.35 \pm .06$ , its bi-serial correlations with all other notations are generally dissimilar to those obtained for speech defect (Table 120, chap. 11x). Since speech defect appears to be correlated only with notations suggestive of low intelligence or constitutional inadequacy, it has been relegated to a subsequent chapter in which physical (or possibly "psychophysical") notations are considered. Stuttering was noted among only 83 cases, or among 3.9 per cent, of our 2,113 White boys. (Within our smaller population of 1,181 White girls there were not sufficient cases to justify computing correlation coefficients.) As an indicator of personality or conduct deviation, stuttering appeared to be of little importance, its correlations (ranging from  $-.05$  to  $.10$ ) with personality-total, conduct-total, and police arrest being low or negligible (Table 116).

Its largest correlation was with speech defect (other than stuttering),  $.35 \pm .06$ . Three notations—psychoneurotic trends, mental conflict, and staff notation of unfavorable conduct prognosis—showed moderate correlations in the .20's.

Stuttering showed moderate negative correlations in the  $-.20$ 's with six miscellaneous notations: bad companions, running with a gang, irregular attendance at school, leading others into bad conduct, brother in penal detention, and possibly with sex delinquency (coitus).

Among the four sex notations for which boys' correlations were calculated, all coefficients were negative and of negligible size except possibly the dubious negative coefficient of  $-.20 \pm .08$  with sex delinquency (coitus).

Among the six physical or psychophysical notations for

-.04; Grouped: disobedient, etc., -.04; Grouped: fighting, etc., -.05; Unhappy, -.05; Question of change of personality, -.05; Changeable moods, -.05; Temper tantrums, -.05; Fighting, -.05; Inattentive in school, -.06; Lying, -.06; Masturbation, -.06; Egocentric, -.06; Grouped: temper, etc., -.06; Question of encephalitis, -.07; Sex denied entirely, -.07; Excuse-forming, -.07; Swearing (general), -.07; Stubborn, -.07; Incurable, -.07; Defiant, -.08; Poor work in school, -.08; Leader, -.09; Truancy from home, -.09; Quarrelsome, -.09; Disturbing influence in school, -.09; Destructive, -.10; Stealing, -.10; Truancy from school, -.10; Overinterest in sex matters, -.10; Grouped: lack of interest in school, etc., -.11; Contrary, -.11; Lack of interest in school, -.12; Attractive manner, -.14; Discord between parents, -.14; Worry over specific fact, -.15; Exclusion from school, -.16; Rude, -.19

which correlations with stuttering were calculated, speech defect yielded the substantial positive correlation of  $.35 \pm .06$ , all other correlations in this field being negligible, ranging from  $-.07$  to  $.07$ .

Among the four home or familial notations brother in penal detention showed the moderate negative coefficient of  $-.20 \pm .06$ , all other correlations in this field being low or negligible.

## CHAPTER LIX

### MISCELLANEOUS PHYSICAL AND PSYCHOPHYSICAL NOTATIONS

In this chapter and the succeeding one are presented fourteen abbreviated tables concerning miscellaneous physical, psychophysical, home, familial, educational, and vocational notations which are not "behavior traits" such as were considered in Tables 6-116, inclusive. A fuller discussion of these fourteen tables would be appropriate in a separate study, in which emphasis could be placed upon causal analysis. In the present volume the intention has been a study of intercorrelations among traits and a consideration of their relative importance or "seriousness." In these fourteen tables all correlation coefficients less than + .20 (except those for personality-total, conduct-total, and police arrest) have been omitted. These smaller coefficients may be found scattered among Tables 6-116, inclusive.

Among these fourteen tables, question or diagnosis of encephalitis is of especial interest because of its concomitants in the personality and conduct fields. Because of the difficulty of making a definite diagnosis among our cases in which actual hospital records were so often lacking, we have employed the words "question of" in order to emphasize the lack of certainty in our consideration of its intercorrelations with other traits. In about 38 per cent of our "encephalitis cases" a definite staff notation of encephalitis or "post-encephalitis" was made, while in the remaining 62 per cent the diagnosis was only tentative or conjectural.<sup>1</sup>

It was noted among 70, or 3.3 per cent, of our 2,113 White boys and among 37, or 3.1 per cent, of our 1,181 White girls. Its

---

<sup>1</sup>A more detailed analysis of our cases of encephalitis is given in the article "The Behavior of Encephalitic Children" by R. L. Jenkins and Luton Ackerson (American Journal of Orthopsychiatry, IV [1934], 499-507).

bi-serial correlations with personality-total were considerable,  $.41 \pm .03$  among boys and  $.52 \pm .04$  among girls. With conduct-total its correlation among girls was fairly substantial,  $.36 \pm .04$ , but only moderate among boys,  $.20 \pm .04$ . With police arrest its correlations were practically zero.

Question or diagnosis of encephalitis showed very high correlations in the .60's with question of change of personality among both sexes and large correlations in the .40's with staff notation of emotional instability (Table 117). It showed meaningful correlations ranging from the .20's to the .40's for such "nervous"

traits as "nervousness," restlessness, irritable temperament, temper tantrums or display (undifferentiated), crying spells, fighting, threatening violence, irregular sleep habits, queer behavior, object of teasing by other children, complaining of bad treatment by other children, and absent-mindedness. Among girls a large additional list of personality and conduct problems showed meaningful correlations ranging from the .20's to the .40's but low and generally positive coefficients below .20 among boys: changeable moods, restlessness in sleep, distractibility, disturbing influence

in school, incorrigibility, loitering or wandering, staying out late at night, disobedience, violence, defiant attitude, rudeness, egocentricity, boastful or "show-off" manner, unpopularity, destructiveness, swearing or bad language (undifferentiated), "spoiled child," finicky food habits, daydreaming, stealing, lying, truancy from home, enuresis, masturbation, and staff notation of unfavorable conduct prognosis.

The correlations for the heterogeneous category, neurological defect (other than formally diagnosed paralysis), drooping of one side of face, dragging one leg, tremors, jerking of limbs, twitching, tic, blinking eye, ptosis, nystagmus, "mask expression," dysdiadokokinesis, etc., are presented in Table 118. Since this

category is so heterogeneous, the correlation coefficients calculated thereon are difficult of interpretation. Their resemblance to those for question or diagnosis of encephalitis (Table 117) is probably due to the fact that the questioned cases of encephalitis form a substantial portion of those included under the rubric neurological defect (unspecified). Since only a very small fraction of our cases showed neurological defects, it was not feasible to obtain a more homogeneous grouping of cases.

The notation headaches or migraine appeared to be of moderate importance with respect to personality and conduct deviation but of negligible significance so far as police arrest or overt juvenile delinquency was concerned (Table 119). Headaches tended to be materially correlated with neurotic and "nervous" behavior traits. In our case-record material it was often difficult to ascertain whether the patient actually suffered physical pain when complaining of headaches or was merely making neurotic complaints.

Speech defect (other than muteness or stuttering), e.g., infantile speech, lisping, mispronunciation, lalling, rhinolalia, "scanning speech," etc., appeared to be of negligible importance

the speech difficulty was a true stuttering or not. It appeared to be characteristic of our younger children, its bi-serial correlations with chronological age among boys and girls respectively being  $-.25 \pm .03$  and  $-.18$  (Table 9, p. 128). It tended to show some moderate correlations with behavior traits associated with lower intelligence or "inadequate" personality.

Convulsions in the case-record material considered in the present volume usually refers to "convulsions in infancy" or "former convulsions," and only seldom were they continuing at the time of the child's examination in the clinic. In only a few instances did they indicate a definite epilepsy. Former convulsions showed only low or negligible correlations with personality or conduct difficulties in our data (Table 121). Several correlations of moderate size ranging from .20 to .30 were found for various "nervous" behavior traits.

The children with syphilis or lues (congenital or acquired) or with positive Wassermann ("2-plus" or more) in our data formed a heterogeneous group because in some instances it was due to a pre-natal or congenital infection while in other cases, especially among girls, it was acquired through specific sex acts by the patient. For this reason its correlation coefficients as shown in Table 122 are difficult to interpret. Its correlations with our three criteria of seriousness were negligible. Its only significant positive correlations were among girls for traits tending to be associated with sex acts.

## CHAPTER LX

### MISCELLANEOUS HOME, FAMILIAL, EDUCATIONAL, AND VOCATIONAL NOTATIONS

In this chapter seven abbreviated tables are presented, concerning home, familial, educational, and vocational notations, together with a brief discussion of each. Minor correlations falling between  $-.19$  and  $+.19$  may be found scattered throughout Tables 6-116, inclusive. The populations upon which these correlations were based are listed in Table 3, p. 55.

Vicious home conditions (exclusive of "immorality"), such as moonshining, bootlegging, gambling, begging, or planning burglaries or hold-ups within the home, showed only low positive correlations ranging from  $.06$  to  $.18$  with our three criteria of seriousness or "ominousness." Among girls there were four positive correlations of substantial size ranging from  $.32$  to  $.41$  with low positive correlations below  $.20$  among boys: staying out late at night, swearing or bad language (undifferentiated), truancy from school, and (calculated for girls only) victim of sex abuse by older child or person (Table 124). A few additional conduct and personality problems showed moderate correlations in the  $.20$ 's among both sexes.

Immoral home conditions (such as prostitution of parent, or sibling living in adultery in the home) among girls showed the moderate tetrachoric correlation of  $.30 \pm .05$  with police arrest (Table 125). All other correlations with personality-total, conduct-total, and police arrest were quite negligible. It showed moderate correlations among girls with sex delinquency (ccitus),  $.29 \pm .03$ , and among boys with overinterest in sex matters,  $.30 \pm .07$ . Among behavior notations of nonsexual nature there were a few moderate correlations in the  $.20$ 's.

The notation brother or half-brother in penal or correctional institution or with police arrest among boys showed the

gang, and leading others into bad conduct. Curiously enough, there were more negative than positive correlations with behavior problems in the personality sphere.

The notation mental deficiency or feeble-mindedness among siblings showed low negative bi-serial correlations with the personality-total and conduct-total and negligible tetrachoric r's with police arrest (Table 127). Among the separate behavior notations it showed a few positive coefficients of significant size with such notations as question of hypophrenia, slow or dull manner, and retardation in school; but the majority of its correlations of significant size were negative in sign.

Discord between parents or foster-parents was noted among 525, or 24.8 per cent, of our 2,113 White boys and among 285, or 24.1 per cent, of our 1,181 White girls. Its correlations with our three criteria of seriousness were low or negligible, ranging

abuse by older child or person. The fact that in our case-record material discord between parents showed so negligible a relationship with personality and conduct problems among our children is contrary to the frequently expressed belief among students of child behavior that parental or familial discord is a potent cause of undesirable behavior. The present writer does not attempt to explain or interpret these correlational results at this time.

Irregular attendance at school or frequent change of school in our data was a heterogeneous notation which, on the one hand, included instances in which a child's truancies may have been so extensive that the continuity of his school career may have been seriously interrupted and, on the other hand, instances in which these irregularities may have been due to inability or unwillingness of the child's parents to keep him in regular attendance. Its correlations with our three criteria of seriousness were low, or at best only moderate (Table 129). The majority of its significant

correlations were for problems associated with his school life, such as refusal to attend school, truancy from school, poor work in school, retardation in school, and traits denoting inadequacy such as loitering or wandering and slovenliness.

The children for whom a request for vocational guidance appeared in the case records formed a vaguely defined group. In some cases the request for vocational guidance was the chief reason for the clinic examination, while in other cases the request was secondary to some behavior or educational problem. Its correlations (Table 130) are reproduced in this volume for the sake of completeness. The present writer at this time is unable to make any interpretations concerning these obtained correlations.

- Breaking into building, box car, etc. See Robbing a building, etc
- Breaking toys. See Destructiveness
- Brother with police arrest or in penal detention, 55, 110, 118, 269, 551-54. Also passim in chaps. ix-lx
- Brown, W., 5
- Bullying, 54, 389. Also passim in chaps. ix-xiii
- "Bumming." See Loitering; Truancy
- Burkey, R. E., 76
- Capricious appetite. See Finicky food habits
- Car stealing. See under Stealing
- Carelessness, etc. See Inefficiency, etc; Irresponsibility
- Case-record data, evaluation of, 24-50
- Categorical trait names versus measured variates, 44-45
- Causal factors, causation, 3-6, 49, 82, 541
- Change of personality, question of, 35, 52, 114, 221, 226-30, 231, 542. Also passim in chaps. ix-lx
- Changeable moods, 52, 114, 136, 229, 231-35, 238. Also passim in chaps. ix-lx
- Chronological age, 8-9, 10, 15, 51, 126-30
- Clean habits, 53, 445-48, 535, 537. Also passim in chaps. ix-lx
- Cleanliness, lack of. See Slovenliness

- Clues, use of correlation coefficients as, 6-7, 18, 69-77
- Coarse versus fine grouping of trait names, 38-43, 135, 298, 455
- Coefficients. See Correlation coefficients
- Coitus. See Sex delinquency (coitus)
- Complaining of bad treatment by other children, 52, 190-92. Also passim in chaps. ix-ix
- Concentration, lack of. See Distractibility
- Conduct prognosis unfavorable. See Unfavorable conduct prognosis
- Conduct-total: correlations with, 14, 37-38, 51, 54, 55, 63, 64, 97-105, 113, 114-21, also passim in chaps. ix-ix; as criterion of "seriousness," 82-83, 85-87, 97-105, 113, 114-21; definition of, 7
- Consistency, 27-34, 46
- Contingency coefficient (Pearson), 16, 20-21
- Contrariness, 52, 219, 332, 347-56. Also passim in chaps. ix-ix
- "Control group" in research, 67-68
- Convulsions, present or former, 55, 548-49. Also passim in chaps. ix-ix
- Correlation: bi-serial  $r$ , 132-33 (see also Bi-serial correlation [Pearson]); intercolumnar, between boys' and girls' coefficients, 96, 105, 113; methods of, 14-23; product-moment, 14-23; tetrachoric, 14-23
- Correlation coefficients, utility and interpretation of, 4-7, 65-77
- Crap-shooting. See Gambling
- Criteria of importance or "seriousness" among traits, 81-87
- Cruelty: to animals, 54 (also passim in chaps. ix-xiii); to younger children, 54, 389 (also passim in chaps. ix-xiii)
- Crying spells, 51, 143-49, 154, 168. Also passim in chaps. ix-ix
- Cursing. See Swearing
- Curvilinearity of regression. See Rectilinearity of regression
- Data, description of, 8-13
- Daydreaming, 52, 115, 142, 200, 206-10. Also passim in chaps. ix-ix
- Deceitfulness. See Lying; Sneakiness
- Defiant attitude, 52, 295, 311, 332, 336, 340-44, 351-56, 392, 462, 466, 516. Also passim in chaps. ix-ix
- Dementia praecox, 54, 84, 92, 114, 127. Also passim in chaps. ix-xiii
- Depressed mood or spells, 51, 64, 84, 92, 93, 114, 135-39, 143, 148, 150, 154, 158, 163, 181, 216-19, 234. Also passim in chaps. ix-ix
- Desirable and indifferent behavior traits, 45-46, 47
- Destructiveness, 53, 84, 332, 336, 340, 350, 376, 378, 384-88, 392, 421, 424, 556. Also passim in chaps. ix-ix
- Dichotomization, point of, 19, 21, 31-32, 39, 74
- Differential completeness of the case-record information, 35-38, 47, 88, 92
- Discontented. See Unhappiness
- Discord between parents, 55, 112, 554-57. Also passim in chaps. ix-ix
- Discouraged. See Depressed mood
- Disobedience, 52, 84, 114, 332-36, 340, 344, 350, 351-56, 384, 396, 400, 461, 516, 519, 533. Also passim in chaps. ix-ix
- Distractibility, 52, 209, 210, 256, 259-62, 280, 462. Also passim in chaps. ix-ix
- Disturbing influence in home, 54. Also passim in chaps. ix-xiii
- Disturbing influence in school, 53, 101, 192, 199, 259, 332, 336, 340, 344, 350, 391, 449, 455, 459-63, 500, 533. Also passim in chaps. ix-ix
- Doering, C. R., 39
- Dull, slow manner. See Slow, dull manner
- Economic status of our cases, 25
- Educational guidance. See Vocational guidance
- Egocentric attitude, 52, 291-95, 298-301, 302, 500. Also passim in chaps. ix-ix
- Elkind, E. B., 39
- Emotional conflict. See Mental conflict
- Emotional instability, 35, 52, 181, 231, 234, 235-39, 306, 309, 542. Also passim in chaps. ix-ix
- Emotional lability. See Emotional instability
- Empirical approach. See Exploratory approach

- Encephalitis, question of, 12, 35, 55, 115, 148-49, 209, 213, 219, 225-26, 235, 259, 269-70, 272, 273, 277, 280, 281, 287, 310, 315, 320, 323, 534, 541-45. Also passim in chaps. ix-lx
- English Convict, The (Goring), 60
- Enuresis, 12, 34, 53, 175, 178, 489-92. Also passim in chaps. ix-lx
- Escape from institution. See Truancy from institution
- Etiology. See Causal factors
- Excitable. See Irritable temperament; Changeable moods; Emotional instability
- Exclusion from school, 53, 309, 369, 424, 461, 525, 531-34. Also passim in chaps. ix-lx
- Excuse-forming attitude, 52, 291, 302-5. Also passim in chaps. ix-lx
- Exhibitionism, 54. Also passim in chaps. ix-xiii
- Exploratory approach in research, 56-62
- Expulsion from school. See Exclusion from school
- Failure to adjust in foster-home, 54. Also passim in chaps. ix-xiii
- Fantastical lying, 53, 185, 357, 361-65, 500, 523. Also passim in chaps. ix-lx
- Fantasying. See Daydreaming; Fantastical lying
- Fearfulness. See Apprehensiveness
- Feeble-mindedness. See Hypophrenia
- Feeble-minded sibling, 55, 64, 554. Also passim in chaps. ix-lx
- Fighting, 53, 115, 192, 195, 276, 280, 294, 295, 326, 366-70, 373, 378-83, 395, 396, 400, 404, 409. Also passim in chaps. ix-lx
- Fine versus coarse grouping of trait names. See Coarse versus fine grouping of trait names
- Finger-sucking. See Thumb-sucking
- Finicky food habits, 10, 53, 489, 494-97, 556. Also passim in chaps. ix-lx
- Fire-setting, 54. Also passim in chaps. ix-xiii
- Fisher, R. A., 20, 22
- "Follower," 45, 46, 53, 510-13. Also passim in chaps. ix-lx
- Forgetfulness. See Absent-mindedness

- Sister, immoral. See Immoral sister
- Sleeplessness. See Irregular sleep habits
- Slovenliness, 45, 53, 442-45, 447-48  
Also passim in chaps. ix-lx.
- Slow, dull manner, 52, 133, 245-47, 252, 253-55. Also passim in chaps. ix-lx
- Smoking, 53, 324, 404, 410, 412-14, 418, 421, 424. Also passim in chaps. ix-lx
- Sneakiness, 54. Also passim in chaps. ix-xiii
- Social worker. See Psychiatric social worker
- Soper, H. E., 14, 22
- Spearman, C., 28, 59, 72
- Speech defect, 55, 538, 545-48. Also passim in chaps. ix-lx. See also Stuttering
- "Spoiled child," 52, 181, 185-89, 497. Also passim in chaps. ix-lx
- Stammering. See Stuttering
- Stanford-Binet examination (1916), 117, 130
- Statistical methods, 14-23
- Staying out late at night, 4, 52, 71, 73, 75, 76, 101, 109, 115, 311, 316, 320-23, 324, 330, 336, 354, 417, 421, 424, 429, 440, 471, 476, 551. Also passim in chaps. ix-lx
- Stealing, 10, 16, 31-32, 34, 52, 70-71, 73-77, 84, 106, 118, 256, 311-15, 316, 320, 324, 336, 340, 354, 357, 364, 417, 419, 424, 473 (also passim in chaps. ix-lx); of an automobile or horse, 54, 84, 106, 115 (also passim in chaps. ix-xiii)
- Stoddill, R. M., 87
- Striking others. See Violence
- Stubbornness, 40, 52, 332, 335, 340, 344-47, 351-56. Also passim in chaps. ix-lx
- "Student," 22
- Stuttering, 53, 538-40, 545-48. Also passim in chaps. ix-lx. See also Speech defect
- Sucking thumb. See Thumb-sucking
- "Sugar hunger," 54. Also passim in chaps. ix-xiii
- Suggestions, use of correlation coefficients as, 69-75
- Sulkiness, 53, 514, 517-20. Also passim in chaps. ix-lx
- Sullenness, 53, 340, 354, 514-17, 519. Also passim in chaps. ix-lx
- Sums-and-differences formula (Spearman), 72-77
- Suppressed manner. See Repressed manner
- Swearing: in general, 53, 84, 101, 115, 199, 302, 319, 336, 354, 366, 373, 378, 380, 384, 392, 396, 400, 404-11, 466, 551 (also passim in chaps. ix-lx); at mother, teacher etc., 54, 102, 404, 407-11 (also passim in chaps. ix-xiii)
- Syphilis. See Lues
- Tables of correlation coefficients, construction of, 65-64
- Talking to self without apparent reason, 54, 84. Also passim in chaps. ix-xiii
- Teasing other children, 53, 192, 196, 389-91, 461. Also passim in chaps. ix-lx
- Temper display, 40-41, 53, 64, 392, 396-403. Also passim in chaps. ix-lx
- Temper tantrums, 40-41, 53, 64, 276, 280, 340, 373, 378, 380, 384, 392-96, 399-403, 404, 410. Also passim in chaps. ix-lx
- Tetrachoric correlation (Pearson). See Correlation, tetrachoric
- "Theoretical maximum correlation," 28
- Thorndike, E. L., 18
- Thrasher, F. M., 42
- Threatening violence, 53, 116, 377-83, 384, 392, 400. Also passim in chaps. ix-lx
- Thumb-sucking, 54. Also passim in chaps. ix-xiii
- Thurstone, L. L., 14, 59
- Tiring easily, 54. Also passim in chaps. ix-xiii
- Truancy: from home, 16, 52, 70-71, 73-77, 84, 101, 106, 115, 311, 316-20, 324, 329, 330-31, 336, 354, 357, 364, 429, 471 (also passim in chaps. ix-lx); from institution, 54 (also passim in chaps. ix-xiii); from school, 52, 70-71, 73-77, 102, 106, 109, 115, 311, 316, 320, 329, 330-31, 336, 340, 354, 357, 364, 417, 421, 424, 429, 476, 551, 558 (also passim in chaps. ix-lx)
- Underweight condition, 55, 550. Also passim in chaps. ix-lx

- Unfavorable conduct prognosis, staff notation of, 52, 235, 306-10, 471, 476, 481, 538. Also passim in chaps. ix-lx
- Unhappiness, 43, 51, 135, 138, 139-43, 148, 171, 206, 216, 219, 556. Also passim in chaps. ix-lx
- Unpleasant nicknaming by other children, object of. See Object of teasing, etc.
- Unpopularity, 52, 115, 192, 197-201, 204-5, 369, 370, 376, 380, 461, 505. Also passim in chaps. ix-lx
- Unresponsiveness. See Seclusiveness
- Untruthfulness. See Lying
- Varying completeness in the case-record data. See Differential completeness, etc.
- Victim of sex abuse, 53, 469, 481, 482-85, 551, 556-57. Also passim in chaps. ix-lx
- Violence, 40, 53, 92, 101, 115, 185, 200, 224, 229, 332, 336, 340, 344, 354, 366, 373-77, 378, 383, 384, 392, 396, 400, 404, 409, 462, 505. Also passim in chaps. ix-lx
- Vocational guidance, request for, 55, 558-59. Also passim in chaps. ix-lx
- Wandering. See Loitering
- Wickman, E. K., 85-87
- Worrisomeness, 51, 138, 150, 161-65, 171. Also passim in chaps. ix-lx
- Worry over some specific fact, 51, 138, 157-65, 181, 445. Also passim in chaps. ix-lx
- Yule's "coefficients of association and colligation," 20-21
